Proposed Changes for SPI-4

Paul Aloisi TI

The driver/receiver electrical changes proposed for SPI-4

The changes are based on the information at the bottom of the first page. 00-227r6, 00-239r1 and SPI-4 R00. Unfortunately there are three camps; Camp 1 - 100 mV receiver requires reducing the cable/system AC loss to 30% with the weak driver, camp 2 - 40 mV receiver AAF recommended the cable/system AC loss 40% (SPI-2/3 losses) with the weak driver and camp 3 - no weak driver and AAF receiver.

This proposal addresses the three camps.

The changes proposed:

Figure 49 Paced Timing diagram and the paragraph under the figure
TBDs replaced a table expect for the free running clock which is 100 mV.

Low Loss (LL)
The signal shall transition for LL (low loss systems) from -100 to +100 mV or +100 to -100 mV in 0 to 3 ns, the waveform between -100 and +100 mV is not otherwise specified. The absolute value of the signals shall remain above the 100 mV level for 1.25 ns at each end of the transition. The absolute value of the signals shall not drop below 30 mV except during the transitions (see 7.3.2).
Normal Loss (NL)
The Free running clock shall transition for NL (normal loss systems) from -100 to +100 mV or +100 to -100 mV in 0 to 3 ns, the waveform between -100 and +100 mV is not otherwise specified. The other signals, the first transition from the multiple bit level shall transition –100 to +40 mV or +100 mV to –40 mV, if there is an immediate transition the +40 mV to –100 mV or –40 mV to +100 mV. The absolute value of the signals shall remain above the 100 mV multiple bits or 40 mV for a single bit level for 1.25 ns at each end of the transition. The absolute value of the signals shall not drop below 30 mV except during the transitions (see 7.3.2).

Weak driver off / AAF Adaptive Active Filter (NP)
The Free running clock shall transition for NP (no weak driver systems) from -100 to +100 mV or +100 to -100 mV in 0 to 3 ns, the waveform between -100 and +100 mV is not otherwise specified. The other signals, the first transition from a multiple bit level shall transition at least 150 mV and shall be a minimum 50 mV from the zero crossing, example –200 mV level shall transition to –50 mV for a valid transition.

The absolute value of the multiple bit signals shall remain above the 100 mV for 1.25 ns at each end of the transition. The absolute value of the signals shall not drop below 30 mV except during the transitions (see 7.3.2).

Figure 51 and 52 Receiver Mask paced data transfer needs to be different for the 3 camps, there should be 3 new masks

![Diagram](image-url)

- **Fast-160 LL Receiver Mask, during the data transitions**
- +/-1.1 volt maximum with reflections

1.1 Volt

- **Negated Signal**
  - 1.25 ns
  - 100 mV
  - 0 Volt
  - -100 mV
  - -1.1 Volt

- **Asserted Signal**
  - 3 ns
  - 30 mV
  - -30 mV

- **Negated Signal**
  - 1.25 ns

The ratio of the Peak before the transition to the Peak after the transition in the 1.25 ns range shall not exceed 4 to 1.

**Not Allowed**

**Tolerated**

**Not Recommended**
Fast-160 Receiver Mask NL, during the data transitions
+/-1.1 volt maximum with reflections

The ratio of the Peak before the transition to the Peak at the end of the next bit time in the 1.25 ns range.

Not Allowed
Annex A

Table 1

First row Maximum -40 mV First bit Fast-160 - Note 6
-100 mV subsequent bits Fast-160 or all bits Fast-80 or slower
Without precomp enabled maximum 50 mV First bit Fast-160 requires AAF – Note 7

Second row Minimum 40 mV First Bit Fast-160 – Note 6
100 mV subsequent bits Fast-160 or all bits Fast-80 or slower
Without precomp enabled maximum -50 mV First bit Fast-160 requires AAF – Note 7

Attenuation (%) Fast-160 Maximum 50% Note 5

Note 5 DC Loss 10%, AC loss 40%, if the AC loss is limited to 30% first bit is the same as the subsequent bits.

Note 6 the free running clock – toggling signal after the first transition must be the 100 mV limits specified by the Fast-80 or slower speeds. These values only apply to isolated transitions.

Note 7 – Weak driver is disabled and AAF (Adaptive Active Filter) receivers used.
Leakage was not consider in V_n (OR-tied signals), leakage can change the bias from the terminators by up to 20 mV

**Note:**
1 - These are the signal levels at the receiver, the system allows 60 mV crosstalk for calculating the minimum driver level.
2 - Measured from the driver to the farthest receiver.
3 - Caused by the addition of device capacitive load (see table 9 for calculations).
4 - This is the difference in voltage signal commons for SCSI devices on the bus (see figure 3).
5 - DC Loss 10%, AC loss 40%, if the AC loss is limited to 30% first bit is the same as the subsequent bits.
6 - The free running clock – toggling signal after the first transition must be the 100 mV limits specified by the Fast-80 or slower speeds. These values only apply to isolated transitions.
7 - Weak driver is disabled and AAF (Adaptive Active Filter) receivers used.
