Subject: **Proposal to replace the TBDs for Fast 160 in SPI-4 and to winnow the options**

The September meeting of T10 admonished the working group to reduce the optional analog requirements for Fast 160 before replacing the remaining TBDs. This proposal does both. For the most part this proposal is a repeat of the content of T10/99-295r5 that was recommended by the working group before values within it were replaced in SPI-4r0 by TBDs. Considerable testing as shown in presentations by Bruce Manildi to the various ad hoc meetings continues to support the proposed values.

In addition the proposal borrows some contributions but not all made by others (e.g., Paul Aloisi, Richard Moore, and Richard Uber). Acceptance of the proposal should satisfy the instruction from the September T10 plenary.

p.s. Although the SPI-3 files were used, clause numbers, figure numbers, and table numbers are as FrameMaker determined and have not been synchronized to SPI-4.
6.3.9 Differential attenuation

The attenuation requirements for differential attenuation are specified in table 28.

Both the per meter and the length equivalent to the terminator to terminator spacing requirements in table 28 shall be simultaneously met.
9.3.4 LVD measurement points

(Skip the timing figure stuff and then:)

Figure 50 shows the LVD signal requirements at the receiving SCSI device with synchronous transfers. During paced transfers with precompensation enabled, SCSI devices shall operate with signals at the receiving SCSI device meeting either figure 51, figure 52, or both. Mask 1 is applicable to signals that have more timing margin than those for mask 2 and allows less amplitude margin than does mask 2. The lower amplitude margin of mask 1 may result in timing margin loss internal to the receiver but is accounted for in the timing budget. The higher amplitude margin of mask 2 should result in less timing margin loss internal to the receiver. For the cases where the data signal remains at a particular bit state without transitions for more than one transfer period, these masks include a variable asserted or negated period as a function of n (the number of transfer periods with adjacent data at the same state).
For Fast 80 the signal shall transition from $-100$ to $+100$ mV or $+100$ to $-100$ mV in 0 to 3 ns, the waveform between $-100$ and $+100$ mV is not otherwise specified. The absolute value of the signals shall remain above the 100 mV level for 1.25 ns at each end of the transition. The absolute value of the signals shall not drop below 30 mV except during the transitions (see 7.3.2).

Proposer’s note: The above text has been moved from below Figure 49 to below Figure 50.
Receiver Mask 1, during the data transitions
±1,1 volt maximum with reflections

Negated signal

\[ 0 \text{ ns} + ((n-1) \times 6.25 \text{ ns}) \]

\[ 0 \text{ ns} + ((n-1) \times 6.25 \text{ ns}) \]

\[ 1 \text{ ns} \]

\[ 4.25 \text{ ns} \]

\[ 4.25 \text{ ns} \]

\[ -1,1 \text{ V} \]

\[ -130 \text{ mV} \]

\[ -30 \text{ mV} \]

\[ 0 \text{ mV} \]

\[ +30 \text{ mV} \]

\[ +130 \text{ mV} \]

\[ \text{Asserted signal} \]

The ratio of the peak before the transition to the peak of the transition in the 2 ns range shall not exceed 4 to 1.

Tolerated

* Not recommended

Figure 1 - LVD receiver mask 1 = Fast 160

Proposer’s note: This is Figure 51.

For Fast 160 the signal shall transition from -130 to +130 mV or +130 to -130 mV in 0 to 4,25 ns, the waveform between -130 and +130 mV is not otherwise specified. The absolute value of the signals shall remain above the 130 mV level for 1 ns at before and after each transition.
Proposer’s note: This is Figure 52.

Alternatively, for Fast 160 the signal shall transition from -80 to +80 mV or +80 to -80 mV in 0 to 3.25 ns, the waveform between -80 and +80 mV is not otherwise specified. The absolute value of the signals shall remain above the 130 mV level for 1.25 ns before and after each transition. The absolute value of the signals shall not drop below 30 mV except during the transitions (see 7.3.2).
Proposer's note: Mask 3 and mask 4 are not proposed to be included in SPI-4. Rather they are illustrations of the application of mask 2 cases where the data is not alternating. Mask 3 is an example of a zero followed by four ones followed by a zero. Mask 4 is an example of a one followed by four zeros followed by a one. Similar masks could be drawn to illustrate the application of mask 1 to cases where the data is not alternating.
Receiver Mask 4, during the data without transitions
±1.1 volt maximum with reflections

Negated signal
0.5 ns + ((4-1) * 6.25 ns) = 19.25 ns

0.5 ns + ((n-1) * 6.25 ns)

The ratio of the peak before the transition to the peak of the transition in the 1.25 ns range shall not exceed 4 to 1.

Annex A Additional requirements for LVD SCSI drivers and receivers

(normative)

A.1 System level requirements

The requirements for LVD SCSI drivers and receivers in this annex are based on the system level requirements stated in table A.1. Some of these requirements are specifically called out in other subclauses while others are derived from bus loading conditions and trade-offs between competing parameters.

Note:
1 - These are the signal levels at the receiver, the system allows 60 mV crosstalk for calculating the minimum driver level.
2 - Measured from the driver to the farthest receiver.
3 - Caused by the addition of device capacitive load (see table 9 for calculations).
4 - This is the difference in voltage signal commons for SCSI devices on the bus (see figure 3).
5 - SPI standards prior to this standard did not account for leakage current.

A.2 Driver requirements

A.2.1 Driver requirements overview

The fundamental requirement for an LVD driver is the generation of a first-step differential output voltage magnitude at the driver connections to the balanced media to achieve required minimum differential signals at every receiver connection to the bus. If a P_EN bit of one was received by a SCSI device during the prior PPR negotiation, the weak driver amplitude shall be a minimum of 50% to a maximum of 66% of the strong driver amplitude after the first bit of a series of adjacent ones or adjacent zeros. Other
characteristics that affect overall noise margin are the common-mode output voltage, the maximum differential output voltage, the driver output impedance, and the output signal wave shape.

The driver requirements are defined in terms of the voltages and currents depicted in figure 43.

Table A.2 - Driver steady-state test limits and conditions and alternating 1/0 data transfer phase

<table>
<thead>
<tr>
<th>Test parameter</th>
<th>Test conditions (figure A.1)</th>
<th>Minimum (mV)</th>
<th>Minimum (mV)</th>
<th>Maximum (mV)</th>
</tr>
</thead>
</table>
| $| V_A | $ | Differential output voltage magnitude (asserted) (note) | $V_1 = 1.056 \text{ V} 
V_2 = 0.634 \text{ V}$ | 320 | 370 | 800 |
| $| V_A | $ | Differential output voltage magnitude (asserted) (note) | $V_1 = 1.866 \text{ V} 
V_2 = 1.444 \text{ V}$ | 320 | 370 | 800 |
| $| V_N | $ | Differential output voltage magnitude (negated) (note) | $V_1 = 1.056 \text{ V} 
V_2 = 0.634 \text{ V}$ | 320 | 370 | 800 |
| $| V_N | $ | Differential output voltage magnitude (negated) (note) | $V_1 = 1.866 \text{ V} 
V_2 = 1.444 \text{ V}$ | 320 | 370 | 800 |
| **Fast < 160** | $| V_A | $ | Differential output voltage magnitude (asserted) | All four above conditions | 0.69 x $| V_N | + 50$ | N/A | 1.45 x $| V_N | - 65$ |
| **Fast 160** | $| V_A | $ | Differential output voltage magnitude (asserted) | All four above conditions | N/A | (0.9 x $| V_N |) - 23$ | (1.11 x $| V_N |)+ 26$ |

Notes:
1) The test circuit (figure A.1) is approximately equivalent to two terminators creating the normal system bias.
2) Including cutback.
3) The test limits shall be within the shaded domain of Figure A.2.

A.2.2 Differential output voltage, $V_s$

This subclause does not specify requirements for drivers with source impedances less than 1000 Ohms.

To assure sufficient voltage to define a valid logic state at any device connection on a fully loaded LVD bus at least a minimum differential output voltage shall be generated. This value shall be large enough that, after allowance for attenuation (AC and DC), reflections, terminator bias difference, and differential noise coupling, $V_s$ is at least 100 mV meets the specified requirements at the device connector to the LVD SCSI bus.

The SCSI device shall also comply with the upper limits for the differential output voltages and to the symmetry of the differential output voltage magnitudes between logic states in order to assure a first-step transition to the opposite logic state.

With the test circuit of figure A.1 and the test conditions V1 and V2 in table A.2 applied, the steady-state
magnitude of the differential output voltage, $V_S$, for an asserted state ($V_A$), shall be greater than or equal to 320 mV for Fast < 160 or 370 mV for Fast 160 and less than or equal to 800 mV. For the negated state, the polarity of $V_S$ shall be reversed ($V_N$) and the differential voltage magnitude shall be greater than or equal to 320 mV for Fast < 160 or 370 mV for Fast 160 and less than or equal to 800 mV. The relationship between $V_A$ and $V_N$ specified in table A.2 and shown graphically in figure A.2 for Fast < 160 and in figure A.3 for Fast 160 shall be maintained.

The assertion drivers and negation drivers require different strengths to achieve the near equality in $V_A$ and $V_N$ shown in figure A.2 and A.3 because the applied V1 and V2 simulate the effects of the bus termination bias.
