 Date: 5 March 2001  
 Subject: SPC-3 Letting persistent reservations ignore target ports

### **Revision History**

Revision 0 (5 March 2001) first revision. Not complete, but as presented in CAP working group.

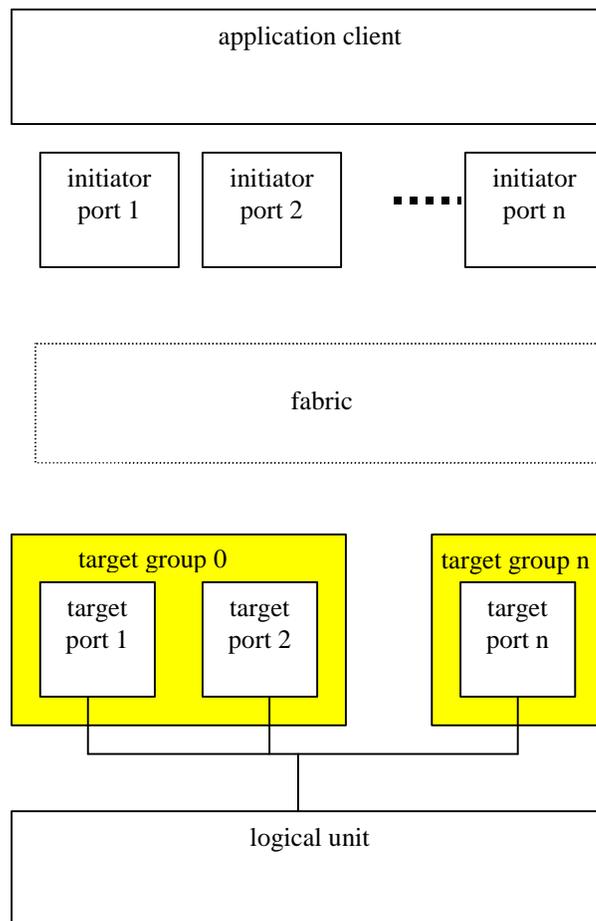

### **Related Documents**

T10/spc2r19 – SCSI Primary Commands revision 19 (by Ralph Weber)

T10/00-232r6 – Asymmetric target behavior (by Ken Moe) (defines target groups)

### **Overview**

SPC-2 requires that logical units remember the target port through which a reservation was made in addition to the initiator port that originated the reservation. An application client wishing to make a reservation needs to run the PERSISTENT RESERVE command through each target port that can route to the logical unit.

In many cases, the logical unit doesn't care which target port the reservation came through. It just wants to distinguish between initiators. Requiring reservation commands for each port burdens the application client with issuing extra commands and burdens the logical unit with extra non-volatile storage.

In some cases, the logical unit may care which target port group (defined in 00-232) a reservation came through, but be capable of treating each target port within the target port group as equivalent.

This proposal allows persistent reservation commands to ignore the target port. There are two approaches:

- a) add a bit to the PERSISTENT RESERVE OUT command indicating the reservation command applies to all target ports within the target port group.
- b) add a mode page with a bit indicating whether the target remembers target ports or not for persistent reservations. The default (zero) is to remember target ports, for compatibility with SPC-2. If the bit is one, the target remembers the target port group rather than the target port. Targets with only one target group effectively ignore the target port altogether.

It also adds text about the current target port requirement, which was previously only mentioned in the multiport section outside the persistent reservation model section.

### **Suggested Changes**

Text is from SPC-2 revision 19. Option a) is documented.

#### **5.5.1 Reservations overview**

Reservations may be used to allow a device server to execute commands from a selected set of initiators. The device server shall reject commands from initiators outside the selected set of initiators by uniquely identifying initiators using protocol specific mechanisms.

'''

#### **5.5.3.1 Overview of the Persistent Reservations management method**

...

The PERSISTENT RESERVE OUT and PERSISTENT RESERVE IN commands provide the basic mechanism for dynamic contention resolution in multiple initiator systems using multiple port targets. Before a persistent reservation may be established, an initiator shall register with a device server using a reservation key. Reservation keys are necessary to allow:

- a) authentication of subsequent PERSISTENT RESERVE OUT commands;
- b) identification of other initiators that are registered;
- c) identification of the reservation key(s) that have an associated reservation;
- d) preemption of a persistent reservation from a failing or uncooperative initiator; and
- e) multiple initiators to participate in a reservation.

The reservation key provides a method for the application client to associate a protocol-independent identifier with an initiator [on a specific port of a device server](#). The reservation key is used in the PERSISTENT RESERVE IN command to identify which initiators are registered and which initiator, if any, holds the reservation. The reservation key is used in the PERSISTENT RESERVE OUT command; to register an initiator, to verify the initiator issuing the PERSISTENT RESERVATION OUT command is registered, and to specify which initiator's registration or persistent reservation to preempt.

...

#### **5.5.3.2 Preserving persistent reservations**

...

The device server shall preserve the following information for each registration cycle across any reset, and if the persist through power loss capability is enabled, across any power cycle:

- a) Initiator identifier;
- [aa\) relative port identifier of the target port;](#)
- b) reservation key; and
- c) when supported by the protocol, the initiator port's world wide identification.

The device server shall preserve the following reservation information across any reset, and if the persist through power loss capability is enabled, across any power cycle:

- a) Initiator identifier;
- aa) [relative port identifier of the target port](#);
- b) reservation key;
- c) scope;
- d) type; and
- e) when supported by the protocol, the initiator port's world wide identification.

For those protocols for which the initiator port's world wide identification is available to the device server the initiator port's world wide identification shall be used to determine if the initiator identifier has changed. This determination shall be made at any time the target detects that the configuration of the system may have changed. If the initiator identifier changed, the device server shall assign the new initiator identifier to the existing registration and reservation of the initiator port having the same world wide identification.

...

#### **5.5.3.4 Registering**

...

In response to a PERSISTENT RESERVE OUT with a REGISTER or a REGISTER AND IGNORE EXISTING KEY service action the device server shall perform a registration by doing the following as an uninterrupted series of actions:

- a) Process the registration request regardless of any persistent reservations;
- b) process the APTPL bit;
- c) ignore the contents of the SCOPE and TYPE fields;
- d) map the reservation key to the registering initiator using the initiator identification and, if available, the initiator port's world wide identification;
- e) register the reservation key without changing any a persistent reservation that may exist; and
- f) retain the reservation key and associated information.

## **5.6 Multiple port and multiple initiator behavior**

SAM-2 specifies the behavior of logical units being accessed by more than one initiator. Additional service delivery ports provide alternate service delivery paths through which the device server may be reached and may also provide connectivity for additional initiators. An alternate path may be used to improve the availability of devices in the presence of certain types of failures and to improve the performance of devices whose other paths may be busy.

If a SCSI device has more than one service delivery port, the arbitration and connection management among the service delivery ports is vendor specific. If one service delivery port is being used by an initiator, accesses attempted through other service delivery port(s) may:

- a) receive a status of BUSY; or
- b) be accepted as if the other service delivery port(s) were not in use.

The device server shall indicate the presence of multiple ports by setting the MULTIP bit to 1 in its standard INQUIRY data.

For the purposes of handling reservations, other initiators are defined as all initiators on the same service delivery port except the initiator holding the reservation and all initiators on all other service delivery ports. Only the following operations allow an initiator to interact with the tasks of another initiator, regardless of the service delivery port:

- a) the PERSISTENT RESERVE OUT with PREEMPT service action preempts persistent reservations for other initiators (see 5.5.3.6.3);
- b) the PERSISTENT RESERVE OUT with PREEMPT AND ABORT service action preempts persistent reservations and all tasks for other initiators (see 5.5.3.6.4);

- c) the PERSISTENT RESERVE OUT with CLEAR service action releases persistent reservations and removes reservation keys for all initiators (see 5.5.3.6.5);
- d) the TARGET RESET task management function releases reservations established by the reserve/release method and removes all tasks for all logical units in the target and for all initiators (see SAM-2). Persistent reservations remain unmodified;
- e) the LOGICAL UNIT RESET task management function releases reservations established by the reserve/release method and removes all tasks for all initiators for the addressed logical unit and any logical units issuing from it in a hierarchical addressing structure (see SAM-2). Persistent reservations remain unmodified; and
- f) the CLEAR TASK SET task management function removes all tasks for the selected logical unit for all initiators. Most other logical unit states remain unmodified, including MODE SELECT parameters, reservations, and ACA (see SAM-2).
