and Mallikarjun Chadalapaka (cbm@rose.hp.com)
Date: 14 July 2002
Subject: T10/02-232r1 SAM-2 SPC-3 SBC-2 SSC-2 Clearing effects of I_T nexus loss

Revision History

02-143r0 (16 April 2002) first revision
02-143r1 (19 April 2002) incorporated comments from Kevin Butt (IBM) on microcode clearing and comments from the clearing effects working group on SAM-2 changes.
02-143r2 (1 May 2002) incorporated comments from May CAP WG. The WG recommended the T10 plenary approve the changes to SPC-3 except for the mode page changes. Work will continue on the SAM-2, SBC-2, and SSC-2 changes.
02-232r0 (19 June 2002) removed accepted SPC-3 changes (incorporated spc3r07) and modified the SAM-2 changes based on internal discussion.
02-232r1 (14 July 2002) incorporated comments from the 6/21 Clearing effects conference call. The group recommended directing the changes to SAM-3 and removing WAKEUP.

Overview

Thanks to Randy Haagens (HP), Cris Simpson (Intel), George Penokie (IBM/Tivoli), Dave Peterson (Cisco), and Ralph Weber (ENDL) for assistance in developing this proposal.

The SCSI architecture model does not describe the effects of logouts, although they have been implemented by numerous protocols. Command sets often indicate an object is cleared based on a “reset”, but don’t mention logouts. Protocol standards are left with large tables listing behavior for commands; these tables are always incomplete and out of date.

This proposal:

- a) Defines “I_T nexus loss” in SAM-3.
- b) Changes current command set (SPC-3, SBC-2, and SSC-2) references to various forms of reset to just “logical unit reset” and/or “power on.”
- c) Adds “I_T nexus loss” to SAM-3 and command sets alongside “logical unit reset” where appropriate.
- d) Describes how “I_T nexus loss” should be defined for the iSCSI, SRP, and SPI-5 protocols.
- e) Cleans up relationships of these actions in SAM-3.

The affected items in SAM-3, SPC-3, SBC-2, and SSC-2 include:

- Background operations
- Deferred errors
- CRN value
- Sense data preservation
- Unit attention generation
- Tasks aborted
- Clear CA or ACA
- Reservations
- Persistent reservations (registration and reservation data, PRGENERATION value)
- Log pages (shared, per-initiator port)
- Mode pages (shared, per-initiator port, per-I_T)
- Asymmetric logical unit access state
- Power condition state
- Alias table associations
- INQUIRY data available without incurring media access delays
- Prevention of medium removal
- Extended Copy status data
- REPORT LUNS data available without incurring media access delays
- Downloaded microcode (effective time, discard partial)
- Mode parameter block descriptors number of blocks field
- Informational Exceptions Control timer/counter
- Access Controls (enabled, TransportID definition, state, proxy tokens, proxy LUN, data persistence)
- XOR data
- Tape capacity persistence
- Tape cleaning requirement persistence

This table summarizes all the things affected by resets that might be affected by “I_T nexus loss.” Some of the items are biased towards clearing, while others are biased towards preserving. Rather than invert the sense to make them all clearing, the sense in the current standards remains. FCP-2 entries marked “CONFLICT” are either complete reversals of the FCP-2 recommendation, or a clearing recommendation where FCP-2 was silent.

NOTE: SPC-3 entries accepted in 02-1345r2 have been removed - this is no longer a complete table.

Table 1. I_T nexus loss summary

What	Where	When (current phrase(s))	Proposed changes	FCP-2 clearing effects table
SAM-2:				
Abort background operations (e.g. format, self-test)	nowhere - SAM-2 5.5 should describe	not mentioned anywhere except by self-test log page in SPC-3 which say “reset” affects it	may be aborted by power on, hard resets, or logical unit resets	not mentioned
Deferred errors cleared	nowhere - SAM-2 5.5 should describe	not mentioned	may be cleared by power on, hard reset, logical unit resets and by I_T nexus losses of the initiator port that sent the command that spawned the background operation	cleared
Reset CRN value	SAM-2 5.1	The initial, wrap, and reset CRN values shall be one	CRN shall be set to one on logical unit reset or I_T nexus loss	set to one
Sense data preserved until	SAM-2 5.8.4.1	it is transferred	add logical unit reset or I_T nexus loss	not mentioned
Generate a unit attention	SAM-2 5.8.5	logical unit has been reset or by a power on reset	logical unit reset or I_T nexus loss	not mentioned
Abort all tasks	SAM-2 5.8.7	logical unit reset	(in new I_T nexus loss section) abort for that initiator on I_T nexus loss	aborted
Clear CA or ACA	SAM-2 5.8.7	logical unit reset	(in new I_T nexus loss section) clear for that initiator on I_T nexus loss	cleared
Release all reservations	SAM-2 5.8.7	logical unit reset	don't mention in SAM-2	cleared
Return operating mode to initial conditions, including mode pages	SAM-2 5.8.7	logical unit reset	don't mention in SAM-2	mode pages cleared

What	Where	When (current phrase(s))	Proposed changes	FCP-2 clearing effects table
SAM-2:				
Set unit attention	SAM-2 5.8.7	logical unit reset	in 5.8.7, specify LOGICAL UNIT RESET OCCURRED additional sense code. in new I_T nexus loss section, specify additional sense code of I_T NEXUS LOSS OCCURRED	not mentioned
SPC-3:				
Mode pages revert to saved/default (shared pages) [SPC-3 doesn't split out shared/per-initiator yet, much less per-I_T nexus]	SPC-3 7.9.2 7.9.6 9.x (both MODE SENSE command and mode parameters sections)	power on or hard reset condition, power up condition or hard reset condition	logical unit reset	cleared on LOGO/PLOGI. For both PRLI and PRLO: keep current values if any still logged in; "not specified" once every initiator logs out. [CONFLICT]
Mode pages revert to saved/ default (per-initiator port pages)	SPC-3 7.9.2 7.9.6	power on or hard reset condition, power up condition or hard reset condition	logical unit reset or I_T nexus loss of all I_T nexuses involving the initiator port	cleared on LOGO/PLOGI. cleared on PRLI; "not specified" on PRLO [CONFLICT]
Mode pages revert to saved/default (per-I_T nexus pages)	SPC-3 7.9.2 7.9.6	power on or hard reset condition, power up condition or hard reset condition	logical unit reset or I_T nexus loss	not mentioned [CONFLICT]
Mode parameter block descriptors number of blocks field (capacity setting) retained	SPC-3 8.4.4.2 8.4.4.3	reset events or power cycles	power cycles, hard resets, logical unit resets, and I_T nexus losses	not mentioned
Informational Exceptions Control mode page timer/counter maintained	SPC-3 8.4.10	power cycles and/or resets	power cycles, hard resets, logical unit resets, and I_T nexus losses	not mentioned [CONFLICT]
SBC-2:				
Mode parameters may also need initialization	SBC-2 4.2.1.5	[after logical unit resets]	after logical unit resets or I_T nexus losses	[see mode pages]
Cause of UNIT ATTENTION	SBC-2 4.2.1.13 4.3.3 4.4.5	logical unit reset or medium change	logical unit reset, I_T nexus loss, or medium change	not mentioned
Retain XOR data across	SBC-2 4.2.3.7	logical unit reset	logical unit reset, I_T nexus loss	retain
SSC-2:				

What	Where	When (current phrase(s))	Proposed changes	FCP-2 clearing effects table
SAM-2:				
Cause of UNIT ATTENTION	SSC-2 4.2.10	logical unit reset or medium change	logical unit reset, I_T nexus loss, or medium change	not mentioned
Write Protect bits set to default state [mode page bits]	SSC-2 4.2.11.3 4.2.11.4 4.2.11.5 4.2.11.6	logical unit reset	[let SPC-3 define mode pages]	[see mode pages]
Unusual per-initiator log page for TapeAlert (see above)	SSC-2 4.2.16.2	[see above]	[see above]	[see above]
SET CAPACITY capacity persists across	SSC-2 7.10	power cycles, logical unit resets	power cycles, hard resets, logical unit resets, I_T nexus losses	not mentioned
Cleaning requirement parameter shall be persistent across	SSC-2 8.2.2	logical unit resets and power cycles	power cycles, hard resets, and logical unit resets, and I_T nexus loss	not mentioned
Device-specific parameters in mode parameter header, mode block descriptor, and data compression mode page retained following	SSC-2 8.3.1	a reset condition	hard reset, logical unit reset, or I_T nexus loss	clear (mode page)
following... report principal density	SSC-2 8.3.1	power on or reset condition	logical unit reset	clear (mode page)
following ... retain knowledge of density code	SSC-2 8.3.1	reset condition	logical unit reset	clear (mode page)
Medium Partition mode page field values...shall not be cleared until	SSC-2 8.3.4	logical unit reset	logical unit reset or until I_T nexus loss of all I_T nexuses	clear (mode page)

Suggested Changes to SAM-3

3.1.x background operation: Operation started by a command that operates after the task containing the command is no longer in the task set (see 5.5).

3.1.x deferred error: Errors generated by background operations (see 5.5).

3.1.39 hard reset: A ~~target-SCSI port~~ action in response to a power on or a reset event in which the ~~target-SCSI~~ port performs the operations described in 5.8.6N.1.3.

3.1.x I T nexus loss: A SCSI port action in response to a hard reset or an I T nexus loss notification event in which the SCSI port performs the operations described in N.1.5.

3.1.x I T nexus loss notification event: A protocol-specific event that triggers an I T nexus loss.

3.1.60 logical unit reset: A logical unit action in response to a logical unit reset event in which the logical unit performs the operations described in 5.8.7N.1.4.

3.1.61 logical unit reset event: An event that triggers a logical unit reset ~~from a logical unit as described in 5.8.7~~. Logical unit reset events include processing the LOGICAL RESET task management function, processing the TARGET RESET task management function, and hard reset.

3.1.p power cycle: Power being removed from and later applied to a SCSI device.

3.1.p power on: A SCSI device action in response to a power on event.

3.1.p power on event: Power being applied to a SCSI device, triggering a power on in the SCSI device.

3.1.84 reset event: A protocol specific event that triggers a hard reset ~~from a SCSI device as described in 5.8.6.~~

3.1.140 wakeup: ~~A SCSI target port returning from the sleep power condition to the active power condition (see SPC-3).~~

3.1.141 wakeup event: ~~An event that triggers a wakeup from a SCSI target port as described in SPC-3.~~

4.14 The SCSI model for distributed communications

The SCSI model for communications between distributed objects is based on the technique of layering. In the layering technique, the initiator and target I/O systems are viewed as being logically composed of the ordered set of subsystems represented for convenience by the vertical sequence shown in figure 25.

..

[Editor's note: 6/21 call asked that something be added to figure 27. TBD.]

5 SCSI Command Model

5.1 The Execute Command remote procedure

...

Command Reference Number (CRN):

When this argument is used, all sequential commands of an I_T_L nexus shall include a CRN argument that is incremented by one. ~~The initial, wrap, and reset CRN values shall be one. CRN shall be set to one for each I T L nexus involving the SCSI port after the SCSI port receives a hard reset or detects I T nexus loss. CRN shall be set to one after it reaches the maximum CRN value supported by the protocol.~~ The CRN value zero shall be reserved for use as defined by the

SCSI protocol. It is not an error for the application client to provide this argument when CRN is not supported by the SCSI protocol or logical unit.

[Editor's note: if a CPQ (HP) letter ballot comment is accepted, CRN will be removed from SAM-2 and left to FCP to define, eliminating the need for this change.]

...

5.5 Task and command lifetimes

This subclause specifies the events delimiting the beginning and end (i.e., lifetime) of a task or tendered SCSI command from the viewpoint of the device server and application client.

The device server shall create a task upon receiving a SCSI Command Received indication unless the command represents a continuation of a linked command as described in 5.1.

The task shall exist until:

- a) The device server sends a SCSI protocol service response for the task of TASK COMPLETE;
or
- b) The task is aborted as described in 5.6.5.8 Command processing considerations and exception conditions.

The application client assumes that the task exists from the time the **Send SCSI Command** SCSI protocol service request is invoked until it receives one of the following target responses:

- a) A service response of TASK COMPLETE for that task;
- b) Notification of a unit attention condition with one of the following additional sense codes:
 - A) COMMANDS CLEARED BY ANOTHER INITIATOR (if in reference to the task set containing the task);
 - B) Any additional sense code whose ADDITIONAL SENSE CODE field contains 29h (e.g., POWER ON, RESET, OR BUS DEVICE RESET OCCURRED; POWER ON OCCURRED; SCSI BUS RESET OCCURRED; BUS DEVICE RESET FUNCTION OCCURRED; DEVICE INTERNAL RESET; TRANSCEIVER MODE CHANGED TO SINGLE-ENDED; ~~or~~ TRANSCEIVER MODE CHANGED TO LVD; or I_T NEXUS LOSS OCCURRED);
- c) A service response of SERVICE DELIVERY OR TARGET FAILURE for the command. In this case, system implementations shall guarantee that the task associated with the failed command has ended;
- d) A service response of FUNCTION COMPLETE following an ABORT TASK task management request function directed to the specified task;
- e) A service response of FUNCTION COMPLETE following an ABORT TASK SET or a CLEAR TASK SET task management function directed to the task set containing the specified task; or
- f) A service response of FUNCTION COMPLETE in response to a LOGICAL UNIT RESET or TARGET RESET task management function directed to the logical unit processing the task.

To the application client, the command is tendered from the time it calls the **Send SCSI Command** SCSI protocol service until one of the above responses or a service response of linked command complete is received.

When a SCSI protocol does not require state synchronization (see 4.6.1), there may be a time skew between the completion of a device server request-response transaction as seen by the application client and device server. As a result, the lifetime of a task or command as it appears to the application client normally is different from the lifetime observed by the device server.

[Editor's note: commands with specific background operations are:

SBC-2: FORMAT UNIT, PRE-FETCH, START STOP UNIT, SYNCHRONIZE CACHE

SSC-2: ERASE, VERIFY, WRITE FILEMARKS, LOCATE, FORMAT MEDIUM, LOAD UNLOAD, REWIND, SET CAPACITY

SPC-3: SEND DIAGNOSTICS

Write commands start background operations if a write-back cache is enabled, too.]

Some commands (e.g., commands with immediate bits like SEND DIAGNOSTIC, or write commands when a write cache is enabled) start background operations that operate after the task containing the command is no longer in the task set. These operations may be aborted by power on, hard resets, or logical unit resets. These operations may generate deferred errors, which are reported with autosense or in sense data for a subsequent completed command (see SPC-3). A deferred error may be cleared by power on, hard reset, logical unit reset, and by I_T nexus loss involving the initiator port that sent the command that spawned the background operation, if the device server has retained that information.

5.8.4.1 Sense data introduction

Sense data shall be made available by the logical unit in the event a command completes with a CHECK CONDITION status or other conditions(?). The format, content and conditions under which sense data shall be prepared by the logical unit are specified in this standard, SPC-2, the applicable device command standard and applicable SCSI protocol standard.

Sense data shall be preserved by the logical unit for the initiator until:

- a) it is transferred ~~by one of the methods listed below;~~ or until
- b) another task from that initiator is entered into the task set;
- c) a logical unit reset occurs; or
- d) I_T nexus loss involving the initiator occurs.

The sense data may be transferred to the initiator through any of the following methods:

- a) The REQUEST SENSE command (see SPC-2);
- b) An asynchronous event report (see 5.8.4.2); or
- c) Autosense delivery (see 5.8.4.3).

The following clauses describe the last two transfer methods.

...

5.8.5 Unit Attention condition

Each logical unit shall generate a unit attention condition whenever it receives a logical unit reset event or an I_T nexus loss notification event whenever the logical unit has been reset (i.e., on a power on, hard reset, logical unit reset, or I_T nexus loss) -as described in N.1.15.8.7 or by a power-on-reset. In addition, a logical unit shall generate a unit attention condition for each initiator port whenever one of the following events occurs:

- a) A removable medium may have been changed;
- b) The mode parameters in effect for this initiator port have been changed by another initiator port;
- c) The version or level of microcode has been changed;
- d) Tasks for this initiator port were cleared by another initiator port;
- e) INQUIRY data has been changed;
- f) The logical unit inventory has been changed;
- g) The mode parameters in effect for the initiator port have been restored from non-volatile memory;
- h) A change in the condition of a synchronized spindle; or
- i) Any other event requiring the attention of the initiator port.

Logical units may queue unit attention conditions. After the first unit attention condition is cleared, another unit attention condition may exist (e.g., a ~~power-on-condition~~unit attention condition with an additional sense code of POWER ON OCCURRED followed by one with an additional sense code of a microcode change conditionMICROCODE HAS BEEN CHANGED).

...

N Notification event services

The SCSI application layer provides these notification event services for the protocol layer to indicate various protocol-specific events:

- a) Nexus Lost(IN(I_T Nexus)); and
- b) Transport Reset(IN(SCSI_Port)).

The services for these events are described below.

Nexus Lost(IN(I_T Nexus))

Input arguments:

I_T Nexus: the specific nexus that is lost.

This notification event service is specified for both initiator devices and target devices. Each protocol defines the conditions, if any, that shall lead to generating this notification event to the application layer.

Transport Reset(IN(SCSI Port))

Input arguments:

SCSI_Port: the specific SCSI port in the SCSI device which is subject to hard reset.

This notification event service is specified for both initiators and targets. Upon receiving this notification event, the SCSI application layer shall behave as if a hard reset has occurred (see N.1.3). Each protocol defines the conditions, if any, that would lead to generating this notification event to the application layer.

N.1 Power on, hard reset, logical unit reset, and I_T nexus loss

N.1.1 Overview

Figure 1 shows the relationships between power on, hard reset, logical unit reset, I_T nexus loss, and their associated events.

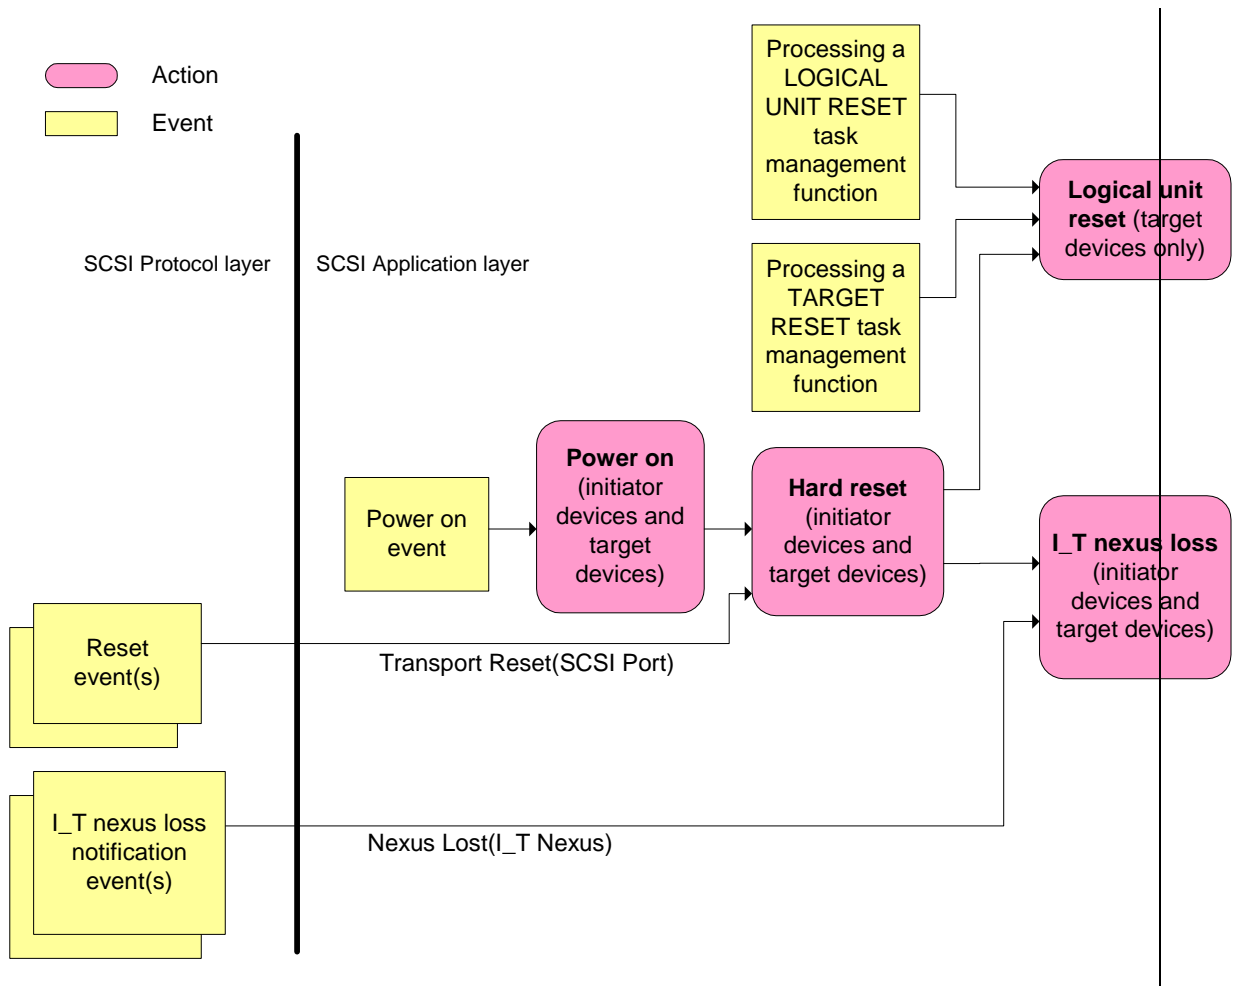

Figure 1. Power on, hard reset, logical unit, and I_T nexus loss relationships

Table xx shows the additional sense code that shall be used when a unit attention is reported for each of these actions by a logical unit. The protocol may define a more specific additional sense code for reset events than SCSI BUS RESET OCCURRED (e.g., TRANSCEIVER MODE CHANGED TO LVD). The actions are sorted from least-specific to most-specific. The most-specific action known to the logical unit shall be reported.

Table xx. Additional sense codes for power on, hard reset, logical unit, and I_T nexus loss

Action	Additional sense code
<u>Logical unit cannot distinguish between the actions</u>	<u>POWER ON, RESET, OR BUS DEVICE RESET OCCURRED</u>
<u>Power on</u>	<u>POWER ON OCCURRED or DEVICE INTERNAL RESET</u>
<u>Hard reset</u>	<u>SCSI BUS RESET OCCURRED or protocol-specific (e.g., TRANSCEIVER MODE CHANGED TO SINGLE-ENDED or TRANSCEIVER MODE CHANGED TO LVD)</u>
<u>Logical unit reset</u>	<u>BUS DEVICE RESET FUNCTION OCCURRED</u>
<u>I_T nexus loss</u>	<u>I_T NEXUS LOSS OCCURRED</u>

The logical unit may use the I_T NEXUS LOSS OCCURRED additional sense code if:
a) the initiator port retrieving the sense data is the initiator port that was involved in the I_T nexus loss, and the logical unit has maintained all per-initiator port state since the I_T nexus loss; and

b) the I_T nexus being used to retrieve the sense data is the same I_T nexus that was lost, and the logical unit has maintained all per-I_T state information since the I_T nexus loss.

Otherwise, it shall use one of the less-specific additional sense codes (e.g., POWER ON OCCURRED).

N.1.2 Power on

[Editor's note: define this here so each protocol standard need not include it in its list of protocol-specific reset events. The additional sense code is defined in N.1.1.]

When a SCSI device is powered on, it shall cause a hard reset.

Power on applies to both SCSI initiator devices and SCSI target devices.

5.8.6 N.1.3 Hard reset

A hard reset is a ~~target SCSI~~ port action in response to a power on or a reset event within the service delivery subsystem. ~~A wakeup event (see 3.1.141) is a reset event.~~ The definition of ~~additional~~ reset events is protocol specific. Each SCSI protocol standard that defines reset events shall specify ~~the a~~ target port's protocol-specific actions in response to reset events.

Hard reset applies to both SCSI initiator devices and SCSI target devices.

~~The A~~ target port's response to a hard reset shall include initiating ~~the equivalent of~~ a logical unit reset for all logical units as described in ~~5.8.7 N.1.4~~.

~~While Although~~ the task manager response to task management requests is subject to the presence of access restrictions, as managed by ACCESS CONTROL OUT commands (see SPC-3), a hard reset ~~in response to a reset event within the service delivery subsystem~~ shall be unaffected by access controls.

When an initiator port performs a hard reset, it should terminate all its outstanding Execute Command remote procedure calls with SERVICE DELIVERY OR TARGET FAILURE.

[Editor's note: if it chooses not to, the commands will time out (if it enforces any ULP timeouts). Thus the rule is not a "shall."]

5.8.7 N.1.4 Logical unit reset

A logical unit reset is:

- a) An action in response to a LOGICAL UNIT RESET task management request (see 6.6) ~~or some other logical unit reset event~~; or
- b) Part of an action in response to a TARGET RESET task management function (see 6.7); or
- c) Part of an action in response to ~~or~~ a hard reset (see ~~5.8.6 N.1.3~~).

Logical unit reset applies only to SCSI target devices.

~~The definition of logical unit reset events is dependent on the SCSI protocol.~~

[Editor's note: Reservation and mode page effects should be left to the command standards to define. Mentioning SAM-3 effects like tasks being aborted is appropriate here. The "operating mode to the appropriate initial conditions" phrase might be worth keeping out of item d).]

To process a logical unit reset the logical unit shall:

- a) Abort all tasks as described in 5.6;
- b) Clear a CA (see 5.8.1.6) or ACA (see 5.8.1.7) condition, if one is present;
- c) ~~Release all reservations established using the reserve/release management method (persistent reservations shall not be affected);~~
- d) ~~Return the logical unit's operating mode to the appropriate initial conditions, similar to those conditions that would be found following device power-on. The MODE SELECT parameters (see SPC-2) shall be restored to their last saved values if saved values have been established.~~

~~MODE SELECT parameters for which no saved values have been established shall be returned to their default values;~~

- e) Set a unit attention condition (see 5.8.5 and N.1.1); ~~and~~
- f) Initiate a logical unit reset for all dependent logical units (see 4.12); ~~and~~

[Editor's note: protocol standards should not define any other effects – only command set standards should do so. Move this into the list:]

~~In addition to the above, the logical unit shall pg)~~ Perform any additional functions required by the applicable command set standards.

N.1.5 I T nexus loss

An I T nexus loss is a SCSI port action in response to a hard reset or an I T nexus loss notification event from the service delivery subsystem. An I T nexus loss notification event is an indication that an I T nexus no longer exists. Protocols may define I T nexus loss notification events.

I T nexus loss applies to both SCSI initiator devices and SCSI target devices.

When a target port detects an I T nexus loss, each logical unit to which the I T nexus has access shall process the I T nexus loss by performing this sequence:

- a) Abort all tasks from the initiator port involved in the I T nexus as described in 5.6;
- b) Clear a CA (see 5.8.1.6) or ACA (see 5.8.1.7) condition, if one is present for the initiator port;
- c) Set a unit attention condition for the initiator port (see 5.8.5 and N.1.1); and
- d) Perform any additional functions required by the applicable command set standards.

If the logical unit retains state information for the I T nexus that is lost, on subsequent I T nexus re-establishment the logical unit should return a unit attention with an additional sense code of I T NEXUS LOSS OCCURRED.

If the logical unit does not retain state information for the I T nexus that is lost, it shall consider the subsequent I T nexus re-establishment, if any, as the formation of a new I T nexus for which there is no past history (e.g., return a unit attention with an additional sense code of POWER ON OCCURRED).

When an initiator port detects an I T nexus loss, it should terminate all its outstanding Execute Command remote procedure calls to that target port with SERVICE DELIVERY OR TARGET FAILURE.

Suggested changes to SPC-3

[Editor's note: Wherever "reset" is listed, change to "logical unit reset" unless it's truly hardware related. This parallels changes already made to SAM-3, SBC-2, SSC-2, and SPI-4.]

[Editor's note: Wherever "logical unit reset" is listed, add "I_T nexus loss" if appropriate.]

...

3.1.34. **hard reset:** A SCSI port action in response to a power on or a reset event in which the SCSI port performs the operations described in SCSI Architecture Model-2.

3.1.38 I_T nexus loss: A SCSI port action in response to a hard reset or an I_T nexus loss notification event in which the SCSI port performs the operations described in SCSI Architecture Model-2.

3.1.x I_T nexus loss notification event: ~~An~~ A protocol specific event that triggers I_T nexus loss as described in SAM-2.

3.1.x **logical unit reset:** A logical unit action in response to a logical unit reset event in which the logical unit performs the operations described in SCSI Architecture Model-2.

3.1.xx logical unit reset event: An event that triggers a logical unit reset as described in SCSI Architecture Model-2.

3.1.63 power cycle: Power being removed from and later applied to a SCSI device.

~~3.1.63 power on: Power being applied to a SCSI device.~~

3.1.63 power on: A SCSI device action in response to a power on event.

3.1.p power on event: Power being applied to a SCSI device.

3.1.72 **reset event:** ~~An~~ A protocol-specific event that triggers a hard reset as described in SCSI Architecture Model-2.

~~3.1.96 wakeup: A target port returning from the sleep power condition to the active power condition (see 5.8).~~

~~3.1.97 wakeup event: An event defined by the protocol that triggers a wakeup from a target port as described in 5.8.~~

...

5.8 Power conditions

The optional power conditions permit the application client to modify the behavior of a target port and/or logical unit in a manner that may reduce power consumption. There is no notification to the application client that one of the power conditions has been entered. Power conditions may be controlled by the START STOP UNIT command for some device types (see SBC-2 or RBC) or the Power Condition mode page for all device types (see 8.4.11). If both methods are being used on the same logical unit then a power condition request made by a START STOP UNIT command shall override the Power Condition mode page's power condition.

No power condition shall affect the service delivery subsystem.

The logical unit power conditions are described in table 15.

Table 15 — Logical unit power conditions

Logical unit power condition	Description
active	The device server is capable of responding to all its supported commands

	including media access requests, and operations complete processing in the shortest time compared to the other power conditions.
idle	The device server is capable of responding to all its supported commands including media access requests. However, a device server in the idle condition may take longer than in the active logical unit power condition to complete processing a command because it may have to activate some circuitry.
standby	The device server is not capable of processing media access commands (e.g., the spindle is stopped).
sleep	The device server is not capable of accepting or processing commands.

~~The logical unit sleep power condition shall only be supported on logical units accessed through target ports using protocols that define wakeup events.~~

Table 16 — Target port power conditions

Target port power condition	Description
active	Logical units to which the target port has access that are not in the sleep logical unit power condition are capable of accepting commands routed from the target port.
idle	Logical units to which the target port has access are not capable of accepting commands routed from the target port. The lowest power consumption, with power applied, occurs in the sleep power condition. The target port requires a wakeup or hard reset to return to the active power condition. The target port enters the sleep power condition only when all the logical units to which it has access have entered the sleep power condition.

~~The target port sleep power condition shall only be supported on target ports using protocols that define wakeup events.~~

Block devices that contain cache memory shall implicitly perform a SYNCHRONIZE CACHE command (see SBC-2 or RBC) for the entire medium prior to entering any power condition that prevents access the media (e.g., the spindle being stopped).

If implemented, the target port shall use the optional Power Condition mode page (see 8.4.11) to control the logical unit power conditions after a ~~wakeup or~~ hard reset until a START STOP UNIT command (see SBC-2 or RBC) is received with the POWER CONDITIONS field set to a value other than 0h or 7h.

~~The state diagram for the target port power conditions is shown in figure 5.~~

Figure 5 — Target port power conditions state diagram

~~The target port power conditions state transitions are:~~

~~**TP0:TP1:** When all logical units in a target port reach the logical unit sleep power condition, the target port transitions to the target device sleep power condition.~~

~~**TP1:TP0:** A wakeup or hard reset returns the target port to the active power condition and returns each logical unit to the power condition (active, idle, or standby) defined by the saved Power Condition mode page parameters.~~

The state diagram for the logical unit power conditions is shown in figure 6.

Figure 6 — Logical Unit power conditions state diagram

[Editor's note; remove state LU8]

The logical unit power conditions state transitions (see table 17) are based on either automatic adjustments or application client controls.

State transition	Description	
	automatic adjustment	application client control
LU5:LU6	While in the active power condition, an idle time-out or a START STOP UNIT command with a power condition code of Ah causes a transition to idle.	While in the active or standby power condition, a START STOP UNIT command with a power condition code of 2h causes a transition to idle.
LU7:LU6	While in the standby power condition, any command that can be processed within the constraints of the idle power condition causes a transition to idle.	
LU6:LU7	While in the idle power condition, a standby time-out or a START STOP UNIT command with a power condition code of Bh causes a transition to idle.	While in the active or idle power condition, a START STOP UNIT command with a power condition code of 3h causes a transition to standby.
LU5:LU7	While in the active power condition, a standby time-out when the IDLE bit is set to zero causes a transition to standby.	
LU6:LU5 LU7:LU5	While in the idle or standby power conditions, any command that exceeds the power constraints of the idle power condition causes a transition to active.	While in the idle or standby power conditions, a START STOP UNIT command with a power condition code of 1h causes a transition to active.
LU6:LU8 LU5:LU8 LU7:LU8	While in the active, idle, or standby power conditions, a START STOP UNIT command with a power condition code of 5h causes a transition to the logical unit sleep power condition. When all logical units in a target port reach the logical unit sleep power condition, the target port transitions to the target device sleep power condition (see TP0:TP1 in figure 5).	
LU8:LUx	A wakeup or hard reset returns the logical unit to the active, idle, or power condition defined by the saved Power Condition mode page parameters.	

7.7 MODE SELECT(6) command

...

~~If a target supports saved mode pages, it may save only one copy of the mode page for each logical unit and have it apply to all initiators, or it may save separate copies for each initiator for each logical unit. Multiple port implementations may save one copy per logical unit and have it apply to all initiators on all ports or save a separate copy per logical unit for each initiator on each port. If separate copies are saved, the target shall maintain separate current values for each combination of initiator and logical unit that it detects. Mode pages that are common to all initiators are not required to have multiple copies.~~

Logical units may maintain current and saved values of each mode page based on any of the policies listed in Table xx.

Table xx. Mode page policies

<u>Mode page policy</u>	<u>Logical unit maintains</u>	<u>When the mode page shall revert to saved values if supported or default values if saved values are not supported</u>
<u>shared</u>	<u>One copy of the mode page.</u>	<u>logical unit reset</u>
<u>per-initiator port</u>	<u>Separate copies of the mode page for each initiator port.</u>	<u>logical unit reset or I_T nexus loss of all I_T nexuses involving the initiator port</u>
<u>per-I_T nexus</u>	<u>Separate copies of the mode page for each I_T nexus.</u>	<u>logical unit reset or I_T nexus loss</u>

If an application client sends a MODE SELECT command that changes any parameters applying to other initiators, the device server shall generate a unit attention condition for all initiators except the one that issued the MODE SELECT command (see SAM-2). The device server shall set the additional sense code to MODE PARAMETERS CHANGED.

~~The target may provide for independent sets of parameters for each attached logical unit or for each combination of logical unit and initiator. If independent sets of parameters are implemented, and if~~ a third-party reservation is requested, the device server shall transfer the set of per-initiator port or per-I_T nexus parameters in effect for the initiator port or I_T nexus that sent the RESERVE command to the parameters used for commands from the third-party device (see 7.26.3).

A page format (PF) bit of zero indicates that all parameters after the block descriptors are vendor specific. A PF bit of one indicates that the MODE SELECT parameters following the header and block descriptor(s) are structured as pages of related parameters and are as specified in this standard.

A save pages (SP) bit of zero indicates the device server shall perform the specified MODE SELECT operation, and shall not save any mode pages. If the ~~target-logical unit~~ implements no distinction between current and saved mode pages and the SP bit is zero, the command shall be terminated with CHECK CONDITION status. The sense key shall be set to ILLEGAL REQUEST, and the additional sense code shall be set to INVALID FIELD IN CDB. An SP bit of one indicates that the device server shall perform the specified MODE SELECT operation, and shall save to a nonvolatile vendor specific location all the saveable mode pages including any sent in the Data-Out Buffer. The SP bit is optional, ~~even when mode pages are supported by the target~~. Mode pages that are saved are identified by the parameter saveable (PS) bit that is returned in the page header by the MODE SENSE command (see 8.4). If the PS bit is set to one in the MODE SENSE data then the mode page shall be saveable by issuing a MODE SELECT command with the SP bit set to one. If the ~~target-logical unit~~ does not implement saved mode pages and the SP bit is set to one, the command shall be terminated with CHECK CONDITION status. The sense key shall be set to ILLEGAL REQUEST, and the additional sense code shall be set to INVALID FIELD IN CDB.

...

7.9 MODE SENSE(6) command

7.9.1 MODE SENSE(6) command introduction

...

An application client may request any one or all of the supported mode pages from the device server. If an application client issues a MODE SENSE command with a page code or subpage code value not implemented by the target, the device server shall return CHECK CONDITION status and shall set the sense key to ILLEGAL REQUEST and the additional sense code to INVALID FIELD IN CDB.

...

7.9.2 Current values

[Editor's note: mode pages need not be affected by I_T nexus loss as specified in FCP-2. It doesn't hurt if they are cleared, because software must assume the worst (that some other initiator changed them while it was logged out. The main concern is that device servers may clear per-initiator data when the initiator departs; otherwise how long is it kept? Assume that FC devices, which are required to clear mode pages when all initiators log out, will provide a unit attention indicating logical unit reset occurred rather than the new I_T nexus loss occurred.]

A PC field value of 00b requests that the device server return the current values of the mode parameters. The current values returned are:

- a) The current values of the mode parameters established by the last successful MODE SELECT command;
- b) The saved values of the mode parameters if a MODE SELECT command has not successfully completed since the ~~last power-on or hard reset condition~~mode parameters were restored to their saved values; or
- c) The default values of the mode parameters if a MODE SELECT command has not successfully completed since the ,if saved values, are not available or not supported~~mode parameters were restored to their default values.~~

...

7.9.6 Initial responses

After a ~~power-up condition or hard reset condition~~logical unit reset, the device server shall respond in the following manner:

- a) If default values are requested, report the default values;
- b) If saved values are requested, report valid restored mode parameters, or restore the mode parameters and report them. If the saved values of the mode parameters are not able to be accessed from the nonvolatile vendor specific location, terminate the command with CHECK CONDITION status and set the sense key set to NOT READY. If saved parameters are not implemented respond as defined in 7.9.5; or
- c) If current values are requested and the current values of the mode parameters have not been sent by the application client (via a MODE SELECT command), the device server may return either the default or saved values, as defined above. If current values have been sent, the current values shall be reported.

...

8.2 Log parameters

8.2.9 Self-Test Results log page

...

[Editor's note: Background self tests are not aborted by I_T nexus losses. Since "reset" was mentioned here, it might be that they are cleared by logical unit resets. However, the May CAP WG didn't agree to that.]

Table 193 - Self-test results values

...

2h The self-test routine was aborted by an application client using a method other than a SEND DIAGNOSTICS command with the SELF-TEST CODE field set to 100b (e.g., by a task management function, by a ~~reset~~logical unit reset, or by issuing an exception command as defined in 5.4.3).

[Editor's note: which task management functions clear background tasks? Are they all the same?]

...

8.4 Mode parameters

8.4.4 Mode parameter block descriptor formats

8.4.4.2 Direct-access device block descriptor format for LONGLBA=0

[Editor's note: mode pages are not cleared by I_T nexus losses]

...

If the SCSI device doesn't support changing its capacity by changing the NUMBER OF BLOCKS field using the MODE SELECT command, the value in the NUMBER OF BLOCKS field is ignored. If the device supports changing its capacity by changing the NUMBER OF BLOCKS field, then the NUMBER OF BLOCKS field is interpreted as follows:

- a) If the number of blocks is set to zero, the device shall retain its current capacity if the block size has not changed. If the number of blocks is set to zero and the block size has changed, the device shall be set to its maximum capacity when the new block size takes effect;
- b) If the number of blocks is greater than zero and less than or equal to its maximum capacity, the device shall be set to that number of blocks. If the block size has not changed, the device shall not become format corrupted. This capacity setting shall be retained through ~~reset events or power cycles~~power cycles, hard resets, logical unit resets, and I_T nexus losses;
- c) If the number of blocks field is set to a value greater than the maximum capacity of the device and less than FFFF FFFFh, then the command is terminated with a CHECK CONDITION status. The sense key is set to ILLEGAL REQUEST. The device shall retain its previous block descriptor settings;
- d) If the number of blocks is set to FFFF FFFFh, the device shall be set to its maximum capacity. If the block size has not changed, the device shall not become format corrupted. This capacity setting shall be retained through ~~reset events or power cycles~~power cycles, hard resets, logical unit resets, and I_T nexus losses.

...

8.4.4.3 Long LBA block descriptor format

If the SCSI device doesn't support changing its capacity by changing the NUMBER OF BLOCKS field using the MODE SELECT command, the value in the NUMBER OF BLOCKS field is ignored. If the device supports changing its capacity by changing the NUMBER OF BLOCKS field, then the NUMBER OF BLOCKS field is interpreted as follows:

- a) If the number of blocks is set to zero, the device shall retain its current capacity if the block size has not changed. If the number of blocks is set to zero and the block size has changed, the device shall be set to its maximum capacity when the new block size takes effect;
- b) If the number of blocks is greater than zero and less than or equal to its maximum capacity, the device shall be set to that number of blocks. If the block size has not changed, the device shall not become format corrupted. This capacity setting shall be retained through ~~reset events or power cycles~~power cycles, hard resets, logical unit resets, and I_T nexus losses;
- c) If the number of blocks field is set to a value greater than the maximum capacity of the device and less than FFFF FFFF FFFF FFFFh, then the command is terminated with a CHECK CONDITION status. The sense key is set to ILLEGAL REQUEST. The device shall retain its previous block descriptor settings;
- d) If the number of blocks is set to FFFF FFFF FFFF FFFFh, the device shall be set to its maximum capacity. If the block size has not changed, the device shall not become format corrupted. This capacity setting shall be retained through ~~reset events or power cycles~~power cycles, hard resets, logical unit resets, and I_T nexus losses.

...

8.4.10 Informational Exceptions Control mode page

The INTERVAL TIMER~~R~~ field indicates the period in 100 millisecond increments for reporting that an informational exception condition has occurred. The device server shall not report informational exception conditions more frequently than the time specified by the INTERVAL TIMER~~R~~ field and shall report them as soon as possible after the ~~timer~~ interval has elapsed. After the informational exception condition has been reported the interval timer shall be restarted. A value of zero or FFFF FFFFh in the INTERVAL TIMER~~R~~ field shall indicate the ~~timer~~ interval time is vendor specific.

The REPORT COUNT field indicates the number of times to report an informational exception condition to the application client. A value of zero in the REPORT COUNT field indicates there is no limit on the number of times the device server reports an informational exception condition.

The maintaining of the interval timer and the report counter across power cycles, hard resets, logical unit resets, and I_T nexus losses is vendor specific.

...

8.4.11 Power Condition mode page

[Editor's note: as in chapter 5, power conditions only relate to hard resets not logical unit resets]

The logical unit shall use the Power Condition mode page to control the power conditions after a power on or a hard reset until a START STOP UNIT command is received that sets power conditions.

...

Suggested changes to SBC-2

[Editor's note: Wherever "logical unit reset" is listed, consider whether "I_T nexus loss" is also appropriate.]

3.1.30. ~~wakeup~~: A target port returning from the sleep power condition to the active power condition (see SPC-3).

3.1.31. ~~wakeup event~~: An event that triggers a wakeup from a target port as described in SPC-3.

4.2.1.5 Initialization

Direct-access block devices may require initialization prior to write or read operations. This initialization is performed by a FORMAT UNIT command. Parameters related to the geometry and performance characteristics may be set with the MODE SELECT command prior to the format operation. Some block devices are initialized by means not specified in this standard. The time when the initialization occurs is specific to the implementation of the direct-access block device.

Block devices using a non-volatile medium may save the parameters and only need to be initialized once. However, some mode parameters may need to be initialized after each logical unit reset. A catastrophic failure of the direct-access block device may require the FORMAT UNIT command to be reissued.

Block devices that use a volatile medium may need to be initialized after each logical unit reset prior to the execution of read or write operations. Mode parameters may also need initialization after logical unit resets or I_T nexus losses.

...

4.2.1.13 Error reporting

If any of the following conditions occur during the execution of a command, the command shall be terminated with CHECK CONDITION status and the sense key shall be set to the appropriate sense key with the appropriate additional sense code for the condition. Some errors may occur after the completion status has already been reported. For such errors, SPC-3 defines a deferred error reporting mechanism. Table 4 illustrates some error conditions and the applicable sense keys. The list does not provide an exhaustive enumeration of all conditions that may cause the CHECK CONDITION status.

Table 4 - Example error conditions

Condition	Sense key
Invalid logical block address	ILLEGAL REQUEST
Unsupported option requested	ILLEGAL REQUEST
Logical unit reset, <u>I_T nexus loss</u> , or medium change since last command from this application client	UNIT ATTENTION
Self diagnostic failed	HARDWARE ERROR
Unrecovered read error	MEDIUM ERROR or HARDWARE ERROR
Recovered read error	RECOVERED ERROR
Overrun or other error that might be resolved by repeating the command	ABORTED COMMAND
Attempt to write on write protected medium	DATA PROTECT

[Editor's note: fix same kind of table in 4.3.3 Table 6, and 4.4.5 Table 8]

4.2.3.7 XOR data retention requirements

The target shall retain XOR data while awaiting retrieval by an XDREAD command until performing one of the following events: a matching XDREAD command, logical unit reset, I_T nexus loss involving the initiator which sent the XDWRITE command, CLEAR TASK SET, ABORT TASK if the task matches the pending XDREAD, or ABORT TASK SET.

5.1.23 START STOP UNIT command

...

If the START STOP UNIT command is issued with the POWER CONDITIONS field set to 1h, 2h, or 3h the block device shall:

- a) change power conditions only on receipt of another START STOP UNIT command or a logical unit reset;
- b) suspend any Power Condition timers (see SPC-3) that are active on receipt of the START STOP UNIT command until another START STOP UNIT command is received that returns control of the power condition to the block device or a logical unit reset occurs;
- c) terminate any command received that requires more power than allowed by the START STOP UNIT command's most recent power condition setting with a CHECK CONDITION status with the sense key set to ILLEGAL REQUEST and the additional sense code set to LOW POWER CONDITION ACTIVE.

Suggested changes to SSC-2

[Editor's note: Wherever "logical unit reset" is listed, consider whether "I_T nexus loss" is also appropriate.]

4.2.10 Error reporting

If any of the following conditions occur during the processing of a command or if a deferred error prevented the command from processing, the device server shall return CHECK CONDITION status. The appropriate sense key and additional sense code should be set. Table 1 illustrates some error conditions and the applicable sense keys. Table 1 does not provide an exhaustive enumeration of all conditions that may cause the CHECK CONDITION status.

Table 4 - Error conditions and sense keys

Condition	Sense key
Unsupported option requested.	ILLEGAL REQUEST
Logical unit reset, I_T nexus loss, or medium change since last command from this initiator.	UNIT ATTENTION
...	

4.2.11.3 Software Write Protect for the device server

[Editor's note: let SPC-3 define mode page behavior]

Software Write Protect for the device server controls write protection for the device server. This method of write protect is optionally controlled from the Control mode page (see SPC-3) or the SWP bit in the Device Configuration mode page (see 8.3.3). Either or both methods may be implemented by the device server. If both methods are implemented, each control bit is independently set. Software write protection exists if either bit is non-zero. The state of software write protect for the device server shall not be recorded on media. The value of the SWP bit may be altered by the application client (if the SWP bit is changeable). ~~The state of each control bit shall be set to its default state after a logical unit reset.~~

4.2.11.4 Associated Write Protect

Associated Write Protect controls write protection for the currently mounted volume as long as the current volume is mounted. The associated write protect state is controlled by the ASOCWP bit in the Device Configuration mode page (see 8.3.3). Associated write protection exists if the ASOCWP bit is non-zero. Associated write protection may be altered by the application client (if the ASOCWP bit is changeable) if a volume is mounted. If a volume is de-mounted ~~or after a logical unit reset occurs~~, associated write protection shall be removed.

4.2.11.5 Persistent Write Protect

Persistent Write Protect controls write protection for the currently mounted volume. The persistent write protect state is controlled by the PERSWP bit in the Device Configuration mode page (see 8.3.3). If enabled, persistent write protection shall exist for the mounted volume until disabled by the application client. The state of persistent write protection shall be recorded with the volume. The device server shall report the PERSWP bit as one when a mounted volume is marked with persistent write protection. If a volume is de-mounted ~~or after a logical unit reset occurs~~, the device server shall report the PERSWP bit as zero prior to the mounting of a volume. The means for recording the state of persistent write protect for the volume may be specified in the applicable recording format standard or be vendor-specific.

4.2.11.6 Permanent Write Protect

Permanent Write Protect controls write protection for the currently mounted volume. The permanent write protect state is controlled by the PRMWP bit in the Device Configuration mode page (see 8.3.3). If enabled, permanent write protection shall exist for the mounted volume until disabled by a vendor-specific method. The state of permanent write protection shall be recorded with the volume. The device server shall report the PRMWP bit as one when a mounted volume is marked with permanent write protection. If a volume is de-mounted ~~or after a logical unit reset occurs~~, the device server shall report the PRMWP bit as zero prior to the mounting of a volume. The means for recording the state of permanent write protect for the volume may be specified in the applicable recording format standard or be vendor-specific. Permanent write protection shall

not be removed by a MODE SELECT command using the PRMWP bit. Methods to remove this protection may or may not exist and are vendor-specific.

...

4.2.16.2 TapeAlert log sense format

The TapeAlert interface to the tape drive is based on a LOG SENSE page (2Eh) containing 64 one-byte flags (see table A.1). The specific conditions for any one flag to be set and cleared are vendor-specific. The minimum subset of flags and basic implementation guidelines are described in table 7.

The TapeAlert data is event based and the page control bits in the LOG SENSE command are not applicable and shall be ignored by the device.

[Editor's note: clear per-initiator log pages on I_T nexus loss]

Each flag shall be cleared in the following circumstances:

- a) at drive power on;
- b) after the TapeAlert log page is read - note in multi-initiator environments the TapeAlert flags shall be cleared on a per-initiator basis such that set flags are still visible to other initiators;
- c) when the specified corrective action has been taken (such as using a cleaning cartridge);
- d) on hard reset, logical unit reset or I_T nexus loss; or
- e) on LOG SELECT reset.

7.10 SET CAPACITY command

[Editor's note: capacity is not affected by I_T nexus loss]

The SET CAPACITY command (see table 46) sets the available medium for the currently mounted volume to a proportion of the total capacity of that volume. Any excess space shall be unavailable on the volume after successful completion of this command until changed by a new SET CAPACITY command. This change shall persist through power cycles, hard resets, logical unit resets, I_T nexus losses, and unloading or reloading of the volume. Other vendor-specific actions such as physical erasure may reset the total capacity of the volume. The method for recording the available capacity and other marks needed to manage the resulting capacity for volume interchange may be specified in a recording format standard or may be vendor-specific.

8.2.2 Sequential-Access Device log page

...

A non-zero value of the cleaning required parameter specifies a condition requiring cleaning has been detected and a subsequent cleaning cycle has not been completed. The cleaning required parameter shall be persistent across power cycles, hard resets, logical unit resets ~~and power eyeles, and I_T nexus loss~~.

8.3.1 Mode parameters overview

This subclause defines the descriptors and pages for mode parameters used with sequential-access devices.

The mode parameter list, including the mode parameter header and mode block descriptor, are described in SPC-3.

The device-specific parameters contained in the mode parameter header, mode block descriptor values, and Data Compression mode page shall be retained following a reset condition hard reset, logical unit reset, or I_T nexus loss (e.g., Target Reset, SCSI Logical Unit Reset, Fibre Channel Reset LIP or PLOGI).

NOTE 44 This is to facilitate continued operation for applications such as backup/restore following a reset event.

...

For the MODE SENSE command, the DENSITY CODE field reflects the current operating density of the logical unit. If a current operating density has not been selected, either because no medium is mounted or because the density of the installed medium has not been determined, the DENSITY CODE field should be set to the principal density code value (see 3.1.45). For some logical units, the principal density code value returned in response to a MODE SENSE command may change dynamically to match the most recently detected density. The DENSITY CODE value returned in response to a MODE SENSE command shall be determined as follows:

- a) following a ~~power on or reset condition occurring~~ logical unit reset occurring while not ready, the device server shall report the principal density;
- b) following a unit attention condition for a not-ready-to-ready transition, the device server shall:
 - A) report the principal density if no attempt has been made by the logical unit to determine the density;
 - B) report the principal density if the logical unit is unable to automatically determine the density from the medium; or
 - C) report the current medium density if the logical unit has determined the density from the medium.
- c) following a successful read operation at or after beginning-of-medium, the device server shall report a density code value reflecting the recorded density of the medium. For some implementations, the logical unit may automatically determine this value from the medium. For devices not capable of automatic density determination, the principal density is reported if the density code value is not provided by the preceding MODE SELECT command;
- d) following an unsuccessful read operation or a successful write operation, while at beginning-of-partition, the device server shall:
 - A) report a density code value as described for item B) if a previous MODE SELECT command has not established a density code for the currently mounted volume; or
 - B) report a density code value as provided by the last successful MODE SELECT command for the currently mounted volume.
- e) following a successful unload operation the device server shall report the most recent density code value as determined by items B) through D) above; or
- f) following a ~~reset condition~~ logical unit reset occurring while ready, the device server shall retain knowledge of the density code as determined by items B) through D) above.

8.3.4 Medium Partition mode page(1)

...

[Editor's note: this seems to be a shared mode page, so I_T nexus loss of all I_T nexuses clears it.]

A partition on format (POFM) bit of one specifies the MODE SELECT command shall not cause changes to the partition sizes or user data, either recorded or buffered. If POFM is set to one, actual media partitioning occurs when the device server receives a subsequent FORMAT MEDIUM command (see 7.2). When the FORMAT MEDIUM command partitions the media, it shall do so based on the contents of the mode data for Medium Partition mode pages (1-4). If POFM is set to one, field values specified by a MODE SELECT command for all Medium Partition mode pages (1-4) shall not be changed by the device server before the media is unloaded or until a logical unit reset or until I_T nexus loss of all I_T nexuses. Some field checking may be performed by the MODE SELECT command. However, there is no guarantee that any subsequent partitioning during a FORMAT MEDIUM command will complete with no errors.

Table 1 - TapeAlert log page parameter codes

...

1Eh Hardware A O C

Recommended application client message:

The tape drive has a hardware fault:

1. Eject the tape or magazine.
2. Reset the drive.
3. Restart the operation.

Probable cause:

The drive has a hardware fault that requires reset to recover.

Suggested changes to SRP

[Editor's note: Cris Simpson will define "I_T nexus loss" as a logout (SRP or IB level) - see 02-127 and 01-328.]

Suggested changes to iSCSI

[Editor's note: Mallikarjun Chadalapaka will define "I_T nexus loss" as session logout - see iSCSI draft 12.]

Suggested changes to SPI-5

[Editor's note: George Penokie will define "I_T nexus loss" as when a reselection timeout occurs.]

Suggested changes to FCP-3

[Editor's note: Dave Peterson will define "I_T nexus loss" as logout.]

[Editor's note: Dave will remove all the SCSI items from the Clearing effects table as suggested below.]

4.9 Clearing effects of task management, FCP, FC-FS, and FC-AL-2 actions

Tables 4 and 5 summarize the FCP target objects that are cleared as a result of Fibre Channel Link actions and SCSI operations, respectively. A 'Y' in the corresponding column of either table indicates the object is cleared to its default, saved, or initial value within the device upon successful completion of the specified action. The clearing actions are applicable only to Sequences and Exchanges associated with Fibre Channel protocol actions. Sequences and Exchanges associated with other actions follow rules specified in FC-FS or other relevant protocol standards. An 'N' in the corresponding column indicates the object is not affected by the specified action. A '-' in the column indicates that the action is not applicable. Rows indicating an effect for all initiator ports have the specified effect on all ports, regardless of the link that attaches the initiator port to the target.

[Editor's note: if CRN is made FCP-specific, then FCP-3 should continue to define its clearing effects. If it stays in SAM-2, FCP-3 should probably be silent.]

Table 4 - Clearing effects of link related functions

Target object	ABTS							
	TPRLO							
	PRLI, PRLO							
	LOGO, PLOGI							
	Failed discovery after OLS							
	Failed discovery after LIP							
	Reset, LIP(y,x)
