Subject: Approved minutes for the SCSI passive interconnect performance working group, PIP, in Santa Ana, CA on August 14-15, 2001

Zane Daggett of Hitachi, chair led the meeting. Bill Ham of Compaq, secretary, took these minutes. There was a good attendance from a broad spectrum of the industry. Paul Aloisi of Texas Instruments hosted the meeting.

Previous approved minutes: 01-191r1

3. Agenda development

The agenda shown was that used (moved by Barnes / Fan). Passed unanimously.

4. Approval of previous minutes

Motion (Ham / Getty) that the draft minutes from the previous meeting be approved as modified. Motion passed unanimously.
The methodology for minutes uses the draft/approved minutes scheme with posting to the t10 web site of the minutes as the vehicle for publication. Postings are announced to the SCSI reflector after the posting is verified to be on the web site.

Minutes will be in .pdf format.

5. Review of action items

Action items were reviewed and the status is listed below in the action items section.

6. Administrative structure:

The present administrative structure is:

Chair: Zane Daggett, Hitachi
Vice Chair: Greg Vaupotic, Amphenol Spectra Strip
Secretary: Bill Ham, Compaq

7. Review of industry activities

Bill Ham briefly reviewed the T10, T11, and SFF activities relating to testing and modeling. He noted that the T11 modeling activity has had its sixth meeting and is in the process of producing its first draft document. The next FCSM meeting is scheduled for T11 week in October 2001.

8. Presentations on new topics

8.1 U640 considerations, Dick Uber, Maxtor

This document, 01s012r0.pdf, was represented in this meeting having been originally presented in Colorado Springs at the STA Tech meeting. Russ Brown made the presentation in the absence of Dick. This presentation noted the challenges presented to the cable plant and the system.

There was straw poll that indicated that dropping single ended in SPI-5 was desirable. Vote was 12/1.

Note that the “s” in the document means STA tech (www.SCSITA.org\STATECH).

8.2 U640 measured data, Russ Brown, Maxtor

Russ went through 01-224r0 that contains preliminary data on swept frequency and a few eye diagrams on cables, backplanes, and combinations. This data showed that severe disturbances are to be expected above 320 MHz for the conditions examined.
It was generally accepted that the test set up used may be suitable as a baseline for specifying the eye diagram and swept frequency testing for the PIP document. These are reproduced below for convenience.

**Cable / Backplane Frequency Response Test Setup**

For cable-only measurements active terminator or resistive loads were used in place of backplane.
9. Presentations on old topics

9.1 Effects of periodic structures continued, Larry Barnes, LSI Logic

9.2 Ultra 640 attenuation values, Larry Barnes

[No new discussion in August - topic is still open]

Larry presented a few slides that claimed that no more than 6dB at any
frequency can be compensated by either precompensation or AAF schemes.
Larry is actioned to put his document on the web site.

The assertion that 6 dB is a fundamental limit was challenged by Maxtor.

Bill Ham pointed out that the limits will be different depending on
whether a precompensation or an AAF scheme is being used.

9.3 Periodic structure swept z vs sample length, Greg Vaupotic
Greg showed several examples where the swept frequency impedance exhibited a very regular but quite unexpected response to the different lengths of sample tested. The samples were twist and flat with the flats spaced at the same interval along the entire length.

Seagate retested some of the samples and noted basic agreement with the results. Greg is actioned to create 01-130r1 containing the essence of the Seagate results.

There was agreement that this material should be included in the PIP document as an informative annex. Greg V is the editor of this annex.

10. Effects of non-uniformities and/or periodic structures

10.1 Effects of periodic structures continued, Larry Barnes, LSI Logic

Larry presented a spreadsheet that reports the loaded impedance and velocity of propagation based on frequency, unloaded impedance, separation of loads, capacitance of loads assuming no stub length. Larry agreed to make this spreadsheet available on the web.

Larry Barnes is actioned to place his spreadsheet on the T10 web site.

11. Round robins

A new document has been created to document the details of the round robin testing activities for PIP that have been substantially completed. All details for completed round robins will be contained in this new document and will be removed from the active minutes. At the moment the only round robin in this category is cable media round robin 1. Please see the new document “PIP round robin testing” for information about cable media round robin 1.

The following motion made in a previous meeting is retained due to its important content for round robin testing.

**Motion Daggett/Martin O that samples used for round robins will be identified by the manufacturer of the samples in the active minutes unless the manufacturer specifically requests that his sample be identified in a way that does not indicate the manufacturer. It is understood that the final published results and details in the “PIP round robin testing” document will not contain any manufacturer identifications.**

Motion passes 11/0/1

11.3. Cable Assembly round robin 1, Martin O., Molex
   11.3.1. Update / con call minutes review, Martin O., Bob G.
11.1 Bulk cable round robin 1

[Data from this round robin has been transferred to 01-076.

Adaptec presented data that does not agree well with other data.  Adaptec did not use the same set up (did not use the baluns) but did use ATN VNA.  See 00-076r1 for details.

Spectra strip data was added to 01-076r1.

This round robin is complete except for one data point from Adaptec.

11.2 Bulk cable round robin 2 (Expanded parameter set), Greg Vaupotic, Amphenol Spectra Strip

[Material in this section is retained in the minutes until such time as the report for this round robin is complete enough to transfer to 01-076.  Progress was made - see section on status]

Round robin 2 is based on a significantly more precise specification of the measurement details than round robin 1.

OBJECTIVE

For several characteristics, determine simplest measurement method which compares favorably to the best method.  This is accomplished by measuring several samples using several methods, with results being compared later.  Most Round-Robin participants will not be able to use all methods; each will do what they can.

DATA PRESENTATION

• Data presented in MS Excel spreadsheets, for later by compilation by coordinator.  Participants not able to present electronically are, of course, permitted to present data as recorded.

• Graphs/plots presented prior to final compilation shall be 1 to 1000 MHz, log frequency, even though impedance data is only collected down to 10 MHz.  This facilitates comparing data sets for resonance effects.

• Report impedance as differential Ohms.  “Attenuation” shows gain as dB / meter.

• Report Propagation time Skew as measured (e.g.: 127 ps / 25 meter length) as table (Excel).

SAMPLES

All samples are 25 meter length.  Unshielded samples (twisted pair ribbons) are to be suspended from ceiling, with minimum of crossovers and keeping sample as spread out as possible (to minimize crosstalk effects).

Sample 1  Round twisted pair cable having overall shield, 28 AWG 7-36 TC (Hitachi)
          Measure pairs 1 (Heat shrink 1), 7 (Heat shrink 2), and 34 (Heat shrink 3) (each pair to be secured with heat shrink tubing)

Sample 2  Round twisted pair cable having overall shield, 30 AWG solid TC (Madison)
Measure pairs 1 (Heat shrink 1), 7 (Heat shrink 2), and 34 (Heat shrink 3) (each pair to be secured with heat shrink tubing)

Sample 3 Twisted pair ribbon having no flats. (Spectra-Strip)
Measure pairs 1, 3, and 5 (wires 1-2, 5-6, and 9-10)

Sample 4 Twisted pair ribbon having flats at TDB inch intervals (Hitachi)
Measure pairs 1, 3, and 5 (wires 1-2, 5-6, and 9-10)

**ATTENUATION**
Record S21 using log scale (really is gain). Use 30 Hz IF BW. Where possible, use 401 points. Record from 1 to 1000 MHz, log sweep. In addition to recording sweep, record actual values (using "markers") at 80, 160, and 200 MHz.

Balun Methods, using fixture described in 00-339r0 (balun with matching resistors). For consistency, use matching network comprised of one 68 \( \Omega \) shunt and two 47 \( \Omega \) series resistors (1/8 W 5% carbon).

**Method A** Calibrate by storing fixture response. Then measure sample. Then remove fixture response. (“normalized”)

**Method B** Full 2-port calibration. Use 121 \( \Omega \pm 1\% \) chip resistor (Panasonic EJR series) for “load”, for “short” solder test points of fixture together, for “open” position matching resistors as will be when measurement is made. For “thru”, attach both fixtures together.

**4-port Network Analyzer Methods:**

**Method C** Full 4-port calibration. Calibrate for 100 \( \Omega \) environment.

**Method D** Full 4-port calibration. Calibrate for 122 \( \Omega \) environment (software “corrects” for \( Z \)).
DIFFERENTIAL IMPEDANCE
Use 30 Hz IF BW. Where possible, use 401 points. Record from 10 to 1000 MHz, log sweep.

Hybrid Junction Method
Method E  See Appendix 1 for outline regarding fixture and calibration.

4-port Network Analyzer Method
Method F  Full calibration of one differential port. Calibrate for 100 Ω environment.

SKEW PAIR to PAIR
Per SPI-3 TDR method. Please record propagation time of each leg of each pair. Pair propagation time is the average of these two readings. Doing this allows us to examine within pair skew.

<table>
<thead>
<tr>
<th>Pair #</th>
<th>Propagation time + signal</th>

APPENDIX 1
Hybrid Junction Test Fixture
The hybrid junction converts an unbalanced 50 Ω input into two balanced 50 Ω outputs (two signals having 180° phase, 100 Ω differential). The selected hybrid junction is the M/A-COM H-183-4. This is specified from 30 MHz to 3 GHz. However, it may be used from 10 MHz to 3 GHz when used with a careful calibration.

OUTLINE for Calibration Procedure
Attach fixture to analyzer port 1. Semi-rigid coax strongly recommended.
Preset Network Analyzer to default condition. Then set analyzer to:
- Power = 10 dBm
- Points = 401
- Linear Sweep
- Start = 10 MHz
- Stop = 1 GHz
- 30 Hz IF BW

With attenuators attached, BUT with semi-rigid fixture removed, calibrate port 1. This is accomplished using precision standards attached to the two attenuators on the right.
Two sets of standards are required.

When finished calibrating port 1, attach semi-rigid coax fixture (which, having no sample attached, is an “open” circuit)
- Set analyzer to look at S11 Phase. Set phase scale to 10° per division.
- Enable port extensions
- Adjust port-1 extension for 0° across the frequency range (expected for an open circuit). This compensates for the fixture’s propagation time. Above 800 MHz, it will not be possible to achieve exactly 0°. This is because the fixture is not a perfect open circuit. The attachment stubs cause small undesired parasitics. (Port extension for above fixture is about 380 ps.)
- Set the analyzer to look at S11. Set Z Reflected = On. Set scale = Linear

Important - The analyzer has been calibrated to 50 Ω. The actual impedance at the calibration plane was, in fact, 100 Ω differential. Multiply measurements by two for differential impedance.

Measurement using Open/Short Method
Two measurements are required for each pair that is examined. First, record the impedance of the pair with the far-end “open”. Then record again with the far end “shorted”. The impedance is then calculated with the following equation:
\[ Z = \sqrt{Z_{\text{OPEN}}(Z_{\text{SHORT}})} \] This is the value to report.

11.2.1 Status of bulk cable round robin 2

Madison (retest) now has the samples and will forward to Hitachi (retest) in the sequence shown in the chart.

All samples are 25 meter length.

Hitachi Cable Manchester: Sample 1

Round twisted pair cable having overall shield, 28 AWG 7-36 TC (Hitachi)

Prep both ends:

pair 1 (Heat shrink 1),
pair 7 (Heat shrink 2),
and pair 34 (Heat shrink 3) (each pair to be secured with heat shrink tubing)

Madison: Sample 2

Round twisted pair cable having overall shield, 30 AWG solid TC (Madison)

Prep both ends:

pairs

1 (Heat shrink 1),
7 (Heat shrink 2),
and 34 (Heat shrink 3) (each pair to be secured with heat shrink tubing)

Spectra-Strip: Sample 3

Twisted pair ribbon having no flats, 30 AWG Solid TC

Zane: Sample 4

Twisted pair ribbon having flats at 250mm intervals (Hitachi)

Seagate has an update in August meeting in the form of 01-256r0.

Differences in the data presentation between the Seagate and the Amphenol of approximately 20 dB were noted. It was determined that this difference is probably due to the attenuation of the test fixture being included in the data presented by Seagate.

This is yet another example of the critical importance of following the details of the instructions for executing both the measurement process and the data presentation process if one desires to have agreement.
Seagate will take the original data, subtract the fixture effects and forward to Greg. Greg is preparing a summary of results.

Greg foresees a follow-on round robin with a more complete suite of tests and draft procedures including both those used in round robin 2 and other tests not included in round robin 2 but viewed as useful.

### 11.3 Backplane round robin 1, Umesh Chandra, Seagate

[New info in August relates to the specifications for the SCSI signal driver board (SSDB) that is required for eye pattern testing.]

This effort is needed to add backplane testing methodology to the test suite. The basic idea is to acquire some small selection of SCSI backplanes and send these around for testing at different companies.

Umesh is actioned to select 2 boards for use in the round robin.

Umesh has documented the procedure in 01-132r0.

Participants include: Seagate, LSI Logic, Maxtor, JPM, Foxconn, IBM?, Compaq?, HP?,

Umesh has certain hardware that could be useful in exciting the interconnect under test. This round robin will focus on the “Data spewing” card (disk drive card) (renamed in this meeting to SSDB) with a data interface through the SCA connector that allows programming of the data pattern through an HBA using the SCSI transport.

Motion Ham / Umesh that PIP will document a cost effective eye diagram based test methodology for passive interconnect that will be part of a test suite for performance requirements.

Motion passes 10/0.

It was agreed in the August 2001 meeting that a SCSI signal driver board (SSDB) will be used for eye diagram based testing. This board should be able to control the signal rise time, signal amplitude, fall back level, and possibly other parameters. A methodology of adjusting the requirements at the receive mask to account for the fact that the SSDB does not deliver the worst case allowed signal will be used.

Present status: LSI has completed the first round and will pass the boards/material to Maxtor. LSI has a “break the seal” type of license for the SSDB.

### 11.4 Cable Assembly round robin 1, Martin O., Molex

[Not discussed in August - material is retained until transferred to the round robin results document.]  

Martin O. presented his view of the content and timing of this round robin. As there was not enough time to explore all the details in this meeting needed to structure a “good” round robin a reduced, two company round robin will be completed before February 2001. Martin agreed to structure a preliminary round robin intended to refine the parameters of
the real cable assembly round robin 1. The companies that will deliver results to the February meeting are Molex and JPM.

As this is the first attempt to do a round robin on cable assemblies and since the details of the tests for cable assemblies are still not defined this round robin must be considered as a preliminary investigation of test methods.

11.4.1 Update / con call minutes review, Martin O., Bob G.

Document contains minutes from two separate teleconference.

Notes by Martin O. from 2/15/01 Teleconference for PIP round robin cable assembly testing.

1. Update on the PIP round robin cable assembly:
   a) The following cable assemblies have been received by Molex:

   Sample A-[30 (7/38) AWG non shielded flat multidrop Micro Quick Twist] Hitachi Cable Manchester
   2m total length built from a 2m section of the 10m supplied. 500mm center to center drops with a total of 5 HD68 connectors

   Sample B-[30 (7/38) AWG non shielded round multidrop] Madison Cable Corporation
   2m total length built from a 2m section of the 10m supplied. 500mm center to center drops total 5 connectors HD68 Connectors

   Sample C-[30 AWG solid non shielded twisted flat point to point] Spectra-Strip (Amphenol) (without flats on the ends)
   6m total length built from a 6m section of the 20m supplied. VHDCI connectors on the ends (last resort HD connectors)

   Sample D-[30 AWG solid shielded round point to point] Madison Cable Corporation
   6m total length made from 6m of a total of 20m supplied. VHDCI connectors on the ends.

   Sample E-[34 AWG solid shielded round point to point] Temp-flex
   6m total length made from 6m of a total of 20m supplied. VHDCI connectors on the ends.

2. There were concerns that the idt termination will be damaged after several repeated plug in and plug out in the course of testing. A couple of remedies were suggested: 1) To make several samples with identical characterizations. 2) To use adapters to protect the damage to the connector/cable termination. 3) To eliminate damaged lines in the course of the round robin and collect data only where the lines are in good condition.

3. Impedance Measurement:
   Network analyzer impedance measurement was ruled out as an option because of measurement difficulties for the sample lengths.
Everyone in the meeting agreed to use TDR measurement instrument. Also everyone confirmed he or she has TEK 11801 available.

There was a measurement resolution concern measuring with launch signals at 1 ns. It was suggested to add impedance measurement at launch signals of 500 ps risetime.

4. Attenuation measurement:
   It was pointed out that the SPI-4 spec recommended attenuation measurement with raw cable lengths that can yield 6 dB loss. Since the cable assemblies are fixed in length, the group plan to come up with measurement method to be reviewed in the next week meeting. This was an action item for Molex.

5. Group member update:

   **Notes by Zane D. from 12/19/00 conference call as amended in this meeting**
   
   1. Discussions on cables to use for the test.
      a. Cable assemblies?
      b. Point to Point!
      c. Multi-drops!

   2. Availability of connectors and tooling.

   3. Cable shipping packaging and total lengths.
      a. See above

   4. Time frame for cable delivery and shipping address.
      a. Send to Bob Gannon
      b. By the 29th of December all samples should be in Bob Gannon’s hands. Attn: Mario Sahagun
         JPM Pantera
         Montemorelos No. 121
         Fracc. Loma Bonita
         Zapopan, Jalisco 45060 Mexico

   5. Run down of tests to be conducted by Molex and JPM.
      a. Attenuation [1MHz to 1Ghz]
      b. Crosstalk [NEXT & FEXT - TDR]
      c. Impedence [Diff- first company to test needs to organize a conf. call to discuss test parameters TDR]
      d. Propagation time [Time Domain TDT] for entire length
      e. Number of pairs to test is 6 pairs. 2 pairs from the center 4 pairs against the shield. In the case of flat cable, test 2 from each edge and ACK and REQ in the inner pairs of the cable.
      f. Basically data pairs 10, 11, 12 & 13 then ACK and REQ pairs.
         However, Bob Gannon can change these parameters if he feels it is necessary. It is requested, though, that we leave ACK and REQ in the pairs identified.

   6. Time frame for phase 1 cable round robin test.
      a. February 6th is the final deadline for testing
      b. It is requested that JPM and Molex complete the testing by the February meeting.
      c. All samples will be sent to Bob Gannon at JPM then built and tested by JPM.
      d. Bob Gannon of JPM will forward samples to Martin O. at Molex.
e. Martin O. of Molex will make fixtures and send them onto Bob Gannon by January 5th.
f. Bob Gannon will need to test and send samples to Martin at Molex by the 16th of January (Bob to coordinate other time arrangements with Martin). Both JPM and Molex will present results at the next meeting in February, schedule in S. California.
g. Ken Flourede Temp-flex to submit sample E to Bob Gannon by Friday Feb 23. Bob will make the assembly and send to Martin at Molex by March 02.

The following is detail of Martin O’s proposed test procedures for cable assembly round robin 1.

**Objective:**
This note describes a set of test to characterize the electrical performance of cable assemblies for the cable assembly round robin test. Test will be conducted at different locations and data and methods compared for measurement data consistencies. This will be accomplished by measuring several samples, and results compared later. Most Round-Robin participant will not be able to conduct all tests, each will do what they can.

**Samples:**
Sample A-[30 (7/38) AWG non shielded flat] Hitachi Cable Manchester Micro Quick Twist with 2m build sampling 10m 500mm center to center drops total 5 cables HD Cables

Sample B-[30 (7/38) AWG non shielded round] Madison Cable Corporation Round non-shielded with 2m build sampling 10m 500mm center to center drops total 5 cables HD Cables

Sample C-[30 AWG solid non shielded round] Spectra-Strip [Amphenol] Flat Twisted cable (with or without flats on the ends) with 6m build sampling 20m Point to point at 6m, VHDCI cables

Sample D-[30 AWG solid shielded round] Madison Cable Corporation Round shielded cable with 6m build sampling 20m, Point to point at 6m, VHDCI cables

**Test Parameter:**
a. Attenuation [1Mhz to 1Ghz]
b. Crosstalk [NEXT & FEXT – TDR]
c. Impedance [Diff- TDR]
d. Propagation time [Time Domain TDT] for entire length
e. Number of pairs to test is 6 pairs. 2 pairs from the center, 4 pairs against the shield. In the case of flat cable, test 2 from each edge and ACK and REQ in the inner pairs of the cable.
f. Basically data pair 10, 11, 12 & 13 then ACK and REQ pairs

**Test Equipment:**
1. Network Analyzer
2. TDR
3. Molex Proprietary Test Fixtures
4. Coax Test Leads
5. Differential Baluns

**Attenuation:**
Frequency domain Measurement conducted in differential mode. Record $S_{21}$ using log scale. Use 30 Hz IF bandwidth. For better resolution, use 1601 points. Record from 1MHz to 1GHz. Use Log frequency sweep. Also record values at 80, 160, 200, and 320 MHz.

**Test Setup:**

![Diagram of test setup]

**Test conditions**
A network analyzer is used both as the source of the test signal and as a means of measuring the cable attenuation.

The cal kit contains the precision coax cables and the connector system whose models are stored in the analyzer memory for error correction purposes.

**Test Fixture Board Validation**
Measure the impedance of the test fixture board with a 35 ps launch signal. The impedance of the SMA or launch pad on the board shall remain in the range of 50 to 65 ohms for a 61 ohm controlled impedance board. See fig. 2 for a comparison profile between traditional and acceptable test fixture board impedance for measurements up to 10 GHz signals. For the case of the traditional impedance profile, use matching impedance network to reduce the effect of the SMA or pad. The blue curve is acceptable. The red curve is not acceptable.

**Figure 2 - Test board validation**

**Measurement Issues:**

For a long electrical delay device such as a cable, the network analyzer presents some unusual measurement problems when operating in swept frequency mode. Often the measured response depends on the analyzer’s swept time, and incorrect data may be obtained. The magnitude of the response can drop at faster sweep rate and look distorted. At slower sweep rate correct magnitude can be measured. The result may indicate that a cable has more loss than it truly does or it may indicate presence of ripples which is truly not there.

The cause of the measurement problem arise when using a network analyzer to measure a device that has long electrical delay, \( dt \), the device’s time delay causes a frequency shift between it’s input and output signals. The frequency shift, \( df \) equals the product of the sweep rate and the time delay.

Since frequency is changing with time as the analyzer sweeps, the time delay of the DUT causes a frequency offset between its input
and output. In the analyzer receiver, the test and reference input signals will differ in frequency by $df$. Because the test signal frequency is slightly different than the receiver frequency, the analyzer will err in measuring its magnitude or phase. The faster the analyzer’s sweep rate the larger $df$ becomes, and the larger the error in the test channel.

To improve the measurement accuracy, decrease the sweep rate or decrease the time delay. We will choose to decrease the time delay. Since the time delay is the property of the test device, the better thing to do is decrease the delay difference between the R channel and the B channel. This can be achieved by adding a length of cable with equal electrical length as the test device. This length of cable can be inserted between the R channel in and out connectors on the front panel of the analyzer. The delay of this cable must be less than 5 usec.

**Differential Impedance:**
The impedance will be measured using a Time Domain Reflectometer (TDR) system. TDR employs a step generator and an oscilloscope to capture signal reflections due to device discontinuities. This test will use a 500 psec risetime step signal for the launch signal. As the step propagates through the test fixture and the cable under test, any discontinuities will cause voltage reflections back into the scope. These reflected voltages are used to calculate the reflection impedance of the cable under test.

**Test conditions**
A Time Domain Reflectometry system (TDR) is used both as the source of the test signal and as a means of measuring the reflected signals of the test device.

Two precision coax cables whose characteristic impedance matches the impedance of the TDR system, are used to connect the test fixture to the TDR system.

The launched signal is adjusted for 500 psec. risetime.

The schedule and sequence is still under development: the first three are Molex, JPM (has it now may go back to Molex for new test fixture, and Madison, Hitachi, Foxconn, TDA, C&M, Tempflex, Amphenol (AIPC)?,

The present (20010612) status: gone to Foxconn (Jason Chou) goes to Madison, next then C&M Some inconsistencies are being found with the attenuation data due to test fixture differences.

**Propagation Time:**
Use the TDR to measure the propagation time. Capture the input signal at the receiver and store in the instrument memory. Connect the cable assembly and capture the output signal.

The cable propagation delay will be determined by establishing the difference between $t_0$ and $t_1$ (See fig. 3). This will yield the cable delay performance.

**Test conditions**

A Time Domain Transmission system (TDT) is used both as the source of the test signal and as a means of measuring the propagation delay of the system.

Two precision coax cables whose characteristic impedance matches the impedance of the TDT system, are used to connect the test fixture to the TDT system.

The combined test system/fixture step response time should be equal to or less than the cable step response time.
**Crosstalk:**
This test will evaluate the cross talk performance for differential pairs of SCSI cable assemblies.

**Test Conditions:**
Source Signal: 504 mV p-p differential
Source Resistance: 100 ohms differential matched to 122 ohm board trace split differential.
Termination Resistance: 122 ohms split differential
Signal risetime: 500 psec. (20 – 80%)
S:G Ratio based on SPI-4 pin-out
Tek 11801C Scope
Proprietary designed test fixture boards, impedance controlled 61 ohm
Single ended.
Impedance matched risetime filters

Bob Gannon agreed to attempt to define a signal degradation test based on eye diagrams and with independent aggressor signals operating during the acquisition of the primary pair under test eye.
12. Proposed new round robins

No new round robins were proposed this meeting. See however, the next item.

13. Frequency dependence of dielectric constant test methodology -
Barnes, LSI Logic; Vaupotic, Spectra strip

Deferred (again) to October due to scheduling issues with available time from Larry Barnes. This work is intended to use the HP polished probe method according to the following table. A round robin is planned when the method is stabilized.

Greg Vaupotic provided swept frequency data from the slab method for several samples. The samples in both pellet and extruded form along with data were provided to Larry B.

This discussion produced collaboration containing the following:

<table>
<thead>
<tr>
<th>Pure polyethylene samples to be provided by Spectra Strip (unlikely to be affected by processing)</th>
<th>Slab method data from Spectra Strip’s supplier measurements</th>
<th>Coax probe method measurements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw material processed into a slab</td>
<td>Spectra strip</td>
<td>NA due to slab samples no longer existing</td>
</tr>
<tr>
<td>Raw material extruded over single conductor 30 AWG with approximately 10 mils dielectric thickness</td>
<td>NA</td>
<td>LSI logic -- strip material off conductor and measure by inserting the probe through slit in the conductor to the opposite side</td>
</tr>
</tbody>
</table>

The range of frequency will be at least 1 MHz to 1 GHz linear sweep.

The samples and slab data have been delivered to Larry.

Greg Vaupotic and Larry Barnes are actioned to complete the work outlined in the above table.

14. Worst case vs spec numbers strategy

[Material is retained until transferred to the PIP document]

In order to ensure that the performance measurements are executed with the most aggressive conditions a set of detailed requirements were developed in this meeting.
14.1 To meet the non-precomp receiver requirements

Aggressor lines (used to generate cross talk noise) shall have 1.6v pp +- 0.1 v differential amplitude with a rise time of 1.0 ns +-0.1 ns at the source. Far end aggressor signals shall not be time correlated to (i.e. not derived from the same timing source) the launch signal used on the pair under test. Time correlation is allowed on near end aggressors.

The pair under test launched signal shall have 740 mv pp +-50mV with a rise time of 1.0ns +-0.1 ns

Max allowed jitter is present in launched signal - receiver requirements adjusted to account for max launch jitter if max jitter is not present in launch signal used for the test.

Data pattern running during the testing shall be 2**7-1???????. [The question marks are needed because this data pattern may not be adequately stressful and data acquisition times are impacted.]

14.2 To meet the precomp receiver requirements

Far end aggressor signals shall have 1.6v pp +- 0.1 v differential amplitude with a rise time of 1.0 ns +-0.1 ns at the source and shall not be time correlated to the launch signal on pair under test)

The launched signal on the pair under test shall use 33% cutback (max amplitude - 33%) with a weak driver at 740 mv pp +-50mV and a rise time of 1.0ns +-0.1 ns

Near end aggressor signals shall use same precomp properties as the driver for the pair under test (time correlation is allowed on the near end).

Max allowed jitter is present in launched signal for the pair under test - receiver requirements are adjusted to account for max launch jitter if max jitter is not present in launch signal used for the test.

There was a significant concern than real interconnect may not pass these test requirements and that some finite error rate be established as acceptable. It was pointed out that to have a finite error rate that some specific distribution and mechanism for errors needs to be established and that the Gaussian content of the jitter in SCSI is very low. Therefore it is not clear that having a finite error rate will help to mitigate the concern. No specific number was suggested in this meeting.

If real interconnect does not pass these tests then one would expect a worst case system to fail.

14.3 Interoperability points
Question: should separable connectors that belong to terminators be considered interoperability points? The group agreed that these connectors should be included in the interoperability suite. (Y)

15. PIP documentation - Daggett

This item was not discussed in the August meeting but clearly need to be updated - a series of special bi monthly editing meetings has been scheduled to address these issues.]

This working group will proceed to develop an internal committee document titled “SCSI Passive Interconnect Performance Requirements” whose schedule is independent from SPI-x standards schedule. Zane Daggett is editor, Bill Ham and Greg Vaupotic are assistant editors. The document will follow the same general format as 99-219rx.

The document number is 00-160rx.

The following describes the document section assignments:

Zane Daggett: Editor in chief
Bill Ham: General and overview
Greg Vaupotic: Bulk cable (both point to point and multidrop)
Bob Gannon: Cable assemblies (both point to point and multidrop)
Larry Barnes: Backplanes

15.1 Topics for consideration for the passive interconnect test document

This section was discussed in earlier meetings and modified slightly in this meeting. It will be retained in the minutes until transferred into the PIP document.

The material in this section was reviewed from the last meeting as possible candidates for consideration for the PIP document 00-160rx.

15.1.1 Components of passive interconnect

The following constitute the basic building blocks of passive interconnect:

media (wire and backplane)
connectors
transition regions (connector termination / comb out / lacing regions / vias)
15.1.2 Instrumentation / measurement methods:

- Baluns
- Eye diagram / signal degradation testing (including cross talk noise)
- Filtering schemes for eye pattern generation

These topics are in addition to other issues already identified for bulk cable.

15.1.3 Acceptable performance values

All level 1 tests will have specific acceptable values proposed.

16. Starting point for specifying application of tests

The following configurations were agreed to be used for the next steps in developing specifications for the application of the tests.

**SIMPLEST POINT TO POINT**

![Simplest Point to Point Diagram]

**SIMPLEST MULTIDROP**

![Simplest Multidrop Diagram]

**UNMATED CONNECTOR**

![Unmated Connector Diagram]

The point to point construction allows inclusion of connectors and transition regions, multiple line cross talk, resonance issues and other issues not previously considered in uniform cable media.

The simplest multidrop construction adds a single connector and greatly increases the number of possible interactions between lines as well as adding a known non-uniformity in addition to the connectors and transitions regions in the point to point construction.

Clearly these simple constructions do not have the desired complexity of some interesting applications. These more complex constructions, such
as backplanes will be considered after we complete these initial constructions. [Note: the complexity for these simple constructions is significantly greater than that previously considered.]

16.1 Definitions for the document – Barnes

Not addressed at this meeting.

17. Architectural definitions

[Retained until transferred to the PIP document]

This refers to issues like defining the test points, nomenclature, and the like. It was decided to use the same conventions commonly used for modeling and transmission lines if possible. Larry B to propose a specific syntax for the next meeting.

All measurements will be through a mated connector. This means that the test fixturing specification will be critical since part of the tested interconnect will remain with the test environment and part will be removable with the IUT.

Zane is creating a summary table for all tests defined above and to start the document.

It was agreed that a special filtering function is needed for some tests to account for the filtering that may occur in the receivers. See 00-149r0 for more detail.

18. Old business

18.1 Definition of the requirements for different configurations

[This topic was addressed again in August and basically ratified. There were however a couple of important tweaks relating to the values at the 1 MHz point – see last two paragraphs of this section.]

The following figure defines the S21 (attenuation/gain) requirements based on three configurations:

• uniform bulk cable used in point to point applications
• non-uniform bulk cable and unpopulated backplanes (no connectors) used for multidrop applications
• populated (with loads) multidrop cable assemblies and backplanes

The curves are based on using a maximum multidrop cable assembly length of 3 meters in non-concatenated applications. For point to point assemblies the maximum length is assumed to be 25 meters. The point to point requirements are the same for the cable assembly and the bulk cable because of the dominance of the cable losses.
Note that the losses for the multidrop configurations are assumed to be significantly caused by resonant effects due to the loads and non-uniformities. More allowance is made for multidrop cable assemblies than for multidrop cable assemblies. Due to the assumed short length for multidrop applications less primary wire loss is expected. The budget for accommodating the resonant losses comes from this lower primary wire losses in the shorter lengths for multidrop.

The low frequency losses are also less for the multidrop applications due to the assumed shorter length.

Note that these performance requirements are independent of length and apply to all physical constructions including backplanes.

Maximum allowable (end to end) S21 vs log frequency

The details of this approach need to be tweaked to allow for a real SQRT f curve fit per the method described in Greg’s detailed description. The D.C. loss numbers do not actually occur at 1 MHz. The mask will use the SQRT f curve fit thru the 12 dB or 6 dB points with an additional requirement that the true D.C. resistance requirements must also be met. The D.C. resistance requirements are based on 4 meter 30 AWG for multidrop and 25 meters 30 AWG for point to point. D.C. resistance requirements will be specified in a separate section.

This general discussion of how the various parts fit together will go into the overview section of the PIP document (Ham editing).
18.2 Skew measurement and specification methodology, Ham

This topic was not discussed in August.

18.3 Standardization of cable sub assemblies, Greg Vaupotic

[No new discussions in August]

[It was agreed in the June meeting that the term “multidrop” would be used to describe constructions that have transition regions in addition to those needed to attach the end connectors.]

Per the last PIP meeting the term media will not be used to refer to bulk cable. Greg noted that the concept of non-uniform media is not really describing the situation. He proposed that the term “cable sub-assembly” be used to describe bulk cable modified to accommodate the next higher level of assembly. Examples of cable sub assemblies are: twist and flat, and round cable prepared for termination.

This terminology was accepted by the PIP working group.

The following material was offered for discussion but was not reviewed in detail. The material in its present state does not represent agreement by the PIP group.

The material following is related to measuring cable subassemblies composed of twisted pairs, having transition regions added to facilitate final-assembly operations.

- SPI-3 specifically excludes these products from the measurement / test specification, recognizing the fact that these are not uniform media, but are subassemblies.
- Large demand exists for non-uniform media.
- No measurement standards exist for these subassemblies. Suppliers and customers are therefore forced to develop ad hoc methods which are often incompatible or contradictory.

Measurement methods must be specified, even if test limits are not presently understood. It will be difficult, perhaps impossible, to eventually develop limits without generally accepted measurement methods.

Simplifying Assumptions (suggested)
These issues were not previously addressed due to the complexity of the subassembly problem. Dramatic simplification might result from the following assumptions, which appear to cover most actual end-use situations.

- Non concatenated
- Maximum length perhaps 4 meters (which significantly exceeds prior PIP/SSM discussions) or maybe determined by an attenuation mask discussed later.

Impedance, Time Domain
A fundamental contradiction exists between the treatment of uniform media (often called “round cable”) and subassemblies.

120 Ω uniform media is always a called 120 Ω, even after transitions have been later added.

But, for example, a 120 Ω twist and flat cable is treated very differently. It is still and always a 120 Ω twist section, but as we place transition regions into a subassembly, the average impedance increases, no surprise. But we no longer call it a 120 Ω. This is highly inconsistent.

For flat cable subassemblies, many users specify the impedance by looking at the average impedance over several regions. Suddenly, the 120 Ω cable becomes 125 or 135 Ω. This is absurd – it’s still a 120 Ω cable with added transition regions.

Greg noted that it may happen that “false” flats may be seen in the TDR trace and that due to roll off in the sample it may not be possible to see a well developed impedance flats for physical flats that are far away from the instrument attachment point.

The use of filtering to emulate the signals that are used in the application also serves well to obscure the impedance of the flat.

[A method to specify the impedance requirements.]

Twisted region

This is the “uniform media” section of the subassembly. Often twist regions are long enough to achieve a reasonably accurate impedance measurement. Very short twist regions are problematic, as reflections induced by discontinuities obscure the region of interest. When the twist region is very short, it might be allowable to measure a twist region of a VERY similar sample having sufficient length for reflections to settle. (This special sample might be produced as part of the same production-run that produced the item of interest.)

Transition region

The first transition region is obscured by fixture effects, while the second region is frequently rounded by attenuation. The transition region is not specified on round-cable assemblies. Why do we specify the transition region here? Might it be sufficient to characterize the transition region?

Impedance, Extended distance

Recommend not including. Evidence indicates subassemblies need to be very long (>> 50 meters) to damp-out measurement resonances. It is extremely impractical to measure very long samples because of the usual lack of shielding. (Understood by anyone who has actually tried to suspend 50+ meters of ribbon from a ceiling, while maintaining distance and minimizing sample crossovers. Even 25 meters is only marginally practical.)

Attenuation
Not all subassembly producers can produce long samples without built-in transition regions. Therefore it might be best to measure attenuation of subassemblies with the transition regions in-place. (25 meter length is feasible.)

Because we might assume a short maximum length, we might specify that the subassembly meet some specified mask. For example, define a maximum attenuation as 6 dB at 200 MHz. For a 4 meter maximum length, this is 1.5 dB / meter maximum at 200 MHz.

Apply a $\sqrt{\text{frequency}}$ relationship as shown:

$$1.5 \, \text{dB} / \, \text{meter} = k \sqrt{f} \quad \text{then} \quad k = 0.106066 \quad \text{with} \ f \ \text{in MHz}$$

$$\text{Mask Attenuation dB} / \, \text{meter} = 0.106066 \sqrt{f} \quad \text{with} \ f \ \text{in MHz}$$

![Figure 4 - Attenuation of 3 different pairs, mask added](image)

This sample from Cable Round Robin 2 would pass a 200 MHz attenuation specification, but would fail the example mask specification for 4 meter length at about 75 MHz. However, at 3 meter length it would be quite good. Based on attenuation only, this example might be marked “for 3 meter max length” (based on all the assumptions).

**Propagation Delay and Skew**

For measurement simplicity, and based on assumed 4 meter maximum length, all delays and skews should be specified as xxx ns / 4 meters or xxx ps.
/ 4 meters. Unit-length specifications are irrelevant based on non concatenated assumption.

**Dielectric Constant Variation with Frequency**

Suggest deleting this requirement for these subassemblies. If assembly is very short and cost sensitive, the group might not want to automatically disallow economical PVC.

When modeling periodic structures, slightly variable permittivity is probably the smallest problem faced by a modeler. (When necessary, reasonably accurate permittivity vs. frequency data could be provided.)
Crosstalk

Below are plots showing FEXT for two structures.

Figure 5 shows flat cable that is twisted along its entire length (no transition regions).
Crosstalk is about – 46 dB at 100 MHz.

Figure 6 shows a subassembly similar to above, but with transition regions on 9.85 inch intervals.
The subassembly’s crosstalk is about – 20 dB at 100 MHz.

The added crosstalk is not due to the “uniform cable”, but instead is due to the structure introduced in the subassembly process.

The same thing would happen to a uniform round media that had transition regions applied at similar intervals!
To be consistent with the specification of uniform media, three alternatives are evident.

- Measure uniform cable similar to that used in subassemblies (e.g.: specially made ribbons without transition regions).
- Don’t measure crosstalk at all under the media specification.
- Measure subassemblies to comply with an as yet to be developed subassembly specification.

19. New business

19.1 Open vs closed systems related to PIP, Daggett/Ham

Open systems are those where all the components with interoperability points may be supplied by different suppliers and the resulting configuration is expected to meet the requirements at all interoperability points.

Closed systems are those that are comprised of components that nominally are similar to those used in open systems but where the exact parts used are always assembled in the same combination and in the same configuration and usually are the same part number from the same supplier.
Open systems require specification at all interoperability points (typically connectors) for any component. Closed systems only require that the signal received at the device meet the specification. Closed systems are much simpler to specify since the only requirement is the received signal.

It was agreed that PIP will remain focused on the open system assumption with the further caveat that open concatenated systems are not included in the initial versions of PIP. [Open concatenated systems are those that allow connection of dissimilar passive interconnects (e.g. flat to round cable, cable to backplane, etc.) AND specify the performance requirements at other than end to end interoperability points.] Closed concatenated systems are comprehended within PIP if the closed system can be accessed with the test fixtures and calibration procedures defined for the open system requirements. [An example of a closed concatenated system is the cable to backplane construction with no requirements specified at the cable/backplane interface unless an active SCSI expander port is present at that interface in which case the system becomes an open system.]

20. Next meetings

Motion Ham/Barnes that beginning Feb 2002 that the PIP working group bimonthly meeting time be reduced to one day and that it alternate with SSM/SSM-2 in terms of being first.

Motion passes: 7/2/1

Zane recommends that the PIP meet on Feb 21, 2002.

Approved schedule:

August 14-15, 2001 9AM to 5 PM 08/14; 9AM to 12PM 08/14 Orange Co, CA (TI)

September 18, 2001 PIP editing, 9AM to 5PM Shrewsbury, MA (Compaq)

October 23-24, 2001 9AM to 5 PM 10/23; 9AM to 12PM 10/24 Colorado Springs, CO (LSI Logic)

Requested schedule:

December 11-12, 2001 9AM to 5 PM 12/11; 9AM to 12PM 12/12 Guadalajara, MX (JPM)

February 21, 2002 (Thurs) 9AM to 5 PM 9AM to 5 PM Santa Cruz, CA (Seagate)

21. Action Items:
21.1 Old action items from previous meetings

Larry Barnes to acquire data from the polished coax probe method for dielectric constant frequency variations.
Status: equipment now in hand, preliminary setup created with software but test results now expected before October, 20xx meeting due to Larry not having adequate bandwidth this period to complete

Zane to provide a methodology specification for the HP slab method for dielectric constant vs. frequency
Status: approx 50% complete

Bill Ham to post the draft minutes to the T10 web site
Status: done 01-191r0

Umesh to propose a set of tests to be used including things like test fixtures and specific slots to be measured for backplane round robin 1.
Status: done - except for S21 tests

Bill Troop to select 1 or 2 boards for use in the backplane round robin 1.
Status: done but boards are not yet supplied to the backplane round robin - focus changed to backplane round robin 2 - Larry Barnes to contact Bob Christopher to determine probable future involvement

Ham to deliver a single 10 slot Compaq backplane (one that is presently shipping) for backplane round robin 1.
Status: carried over - focus changed to backplane round robin 2

Bob Gannon to attempt to define a signal degradation test based on eye diagrams and with independent aggressor signals operating during the acquisition of the primary pair under test eye.
Status: partially done - Bob to adopt Umesh’s basic approach in anticipation of an SSDB being available from LSI and /or others.

Greg Vaupotic and Larry Barnes to complete the work outlined in the table relating to the frequency dependence of dielectric constant.
Status: slab method data and samples sent to Larry - still need the probe method measurements - Greg’s part is done

21.2 New actions from this meeting

Bill Ham to post the minutes to the T10 web site
Status: new

Larry Barnes and Umesh Chandra to determine the availability/acquisition/development/support etc. of viable SCSI signal driver boards (SSDB) for use in eye diagram and cross talk testing
Status: LSI Logic has suitable prototypes and is developing new versions but commitment to general availability has not yet been established, Seagate has also indicated possibility of being a co-developer/supplier of such boards

Motion Ham/Daggett that PIP adopt the name/acronym “SCSI signal driver boards (SSDB)” to describe the function formerly termed “spewing board”.

Motion passes: 7/3/1
Larry Barnes to place his spreadsheet relating to effects of periodic structures on the T10 web site. 
Status: carried over from the April meeting

Greg V to create 01-130r1 containing the essence of the Seagate results relating to effects of sample length on impedance. 
Status: new

Greg V. to create an informative annex relating to the effects of sample length for samples with periodic structure. 
Status: new

Larry B to propose a specific syntax for PIP definitions based on those accepted for the SSM document for the next meeting. 
Status: new

Ham to create a draft of the overview section for the PIP document

Status: new

22. Adjourn

The meeting adjourned at 12:30PM on August 15, 2001
